

# DARK MATTER, RADIO ASTRONOMY, AND HIGH-THROUGHPUT COMPUTING

Michael N. Martinez, UW Madison Dept. of Physics

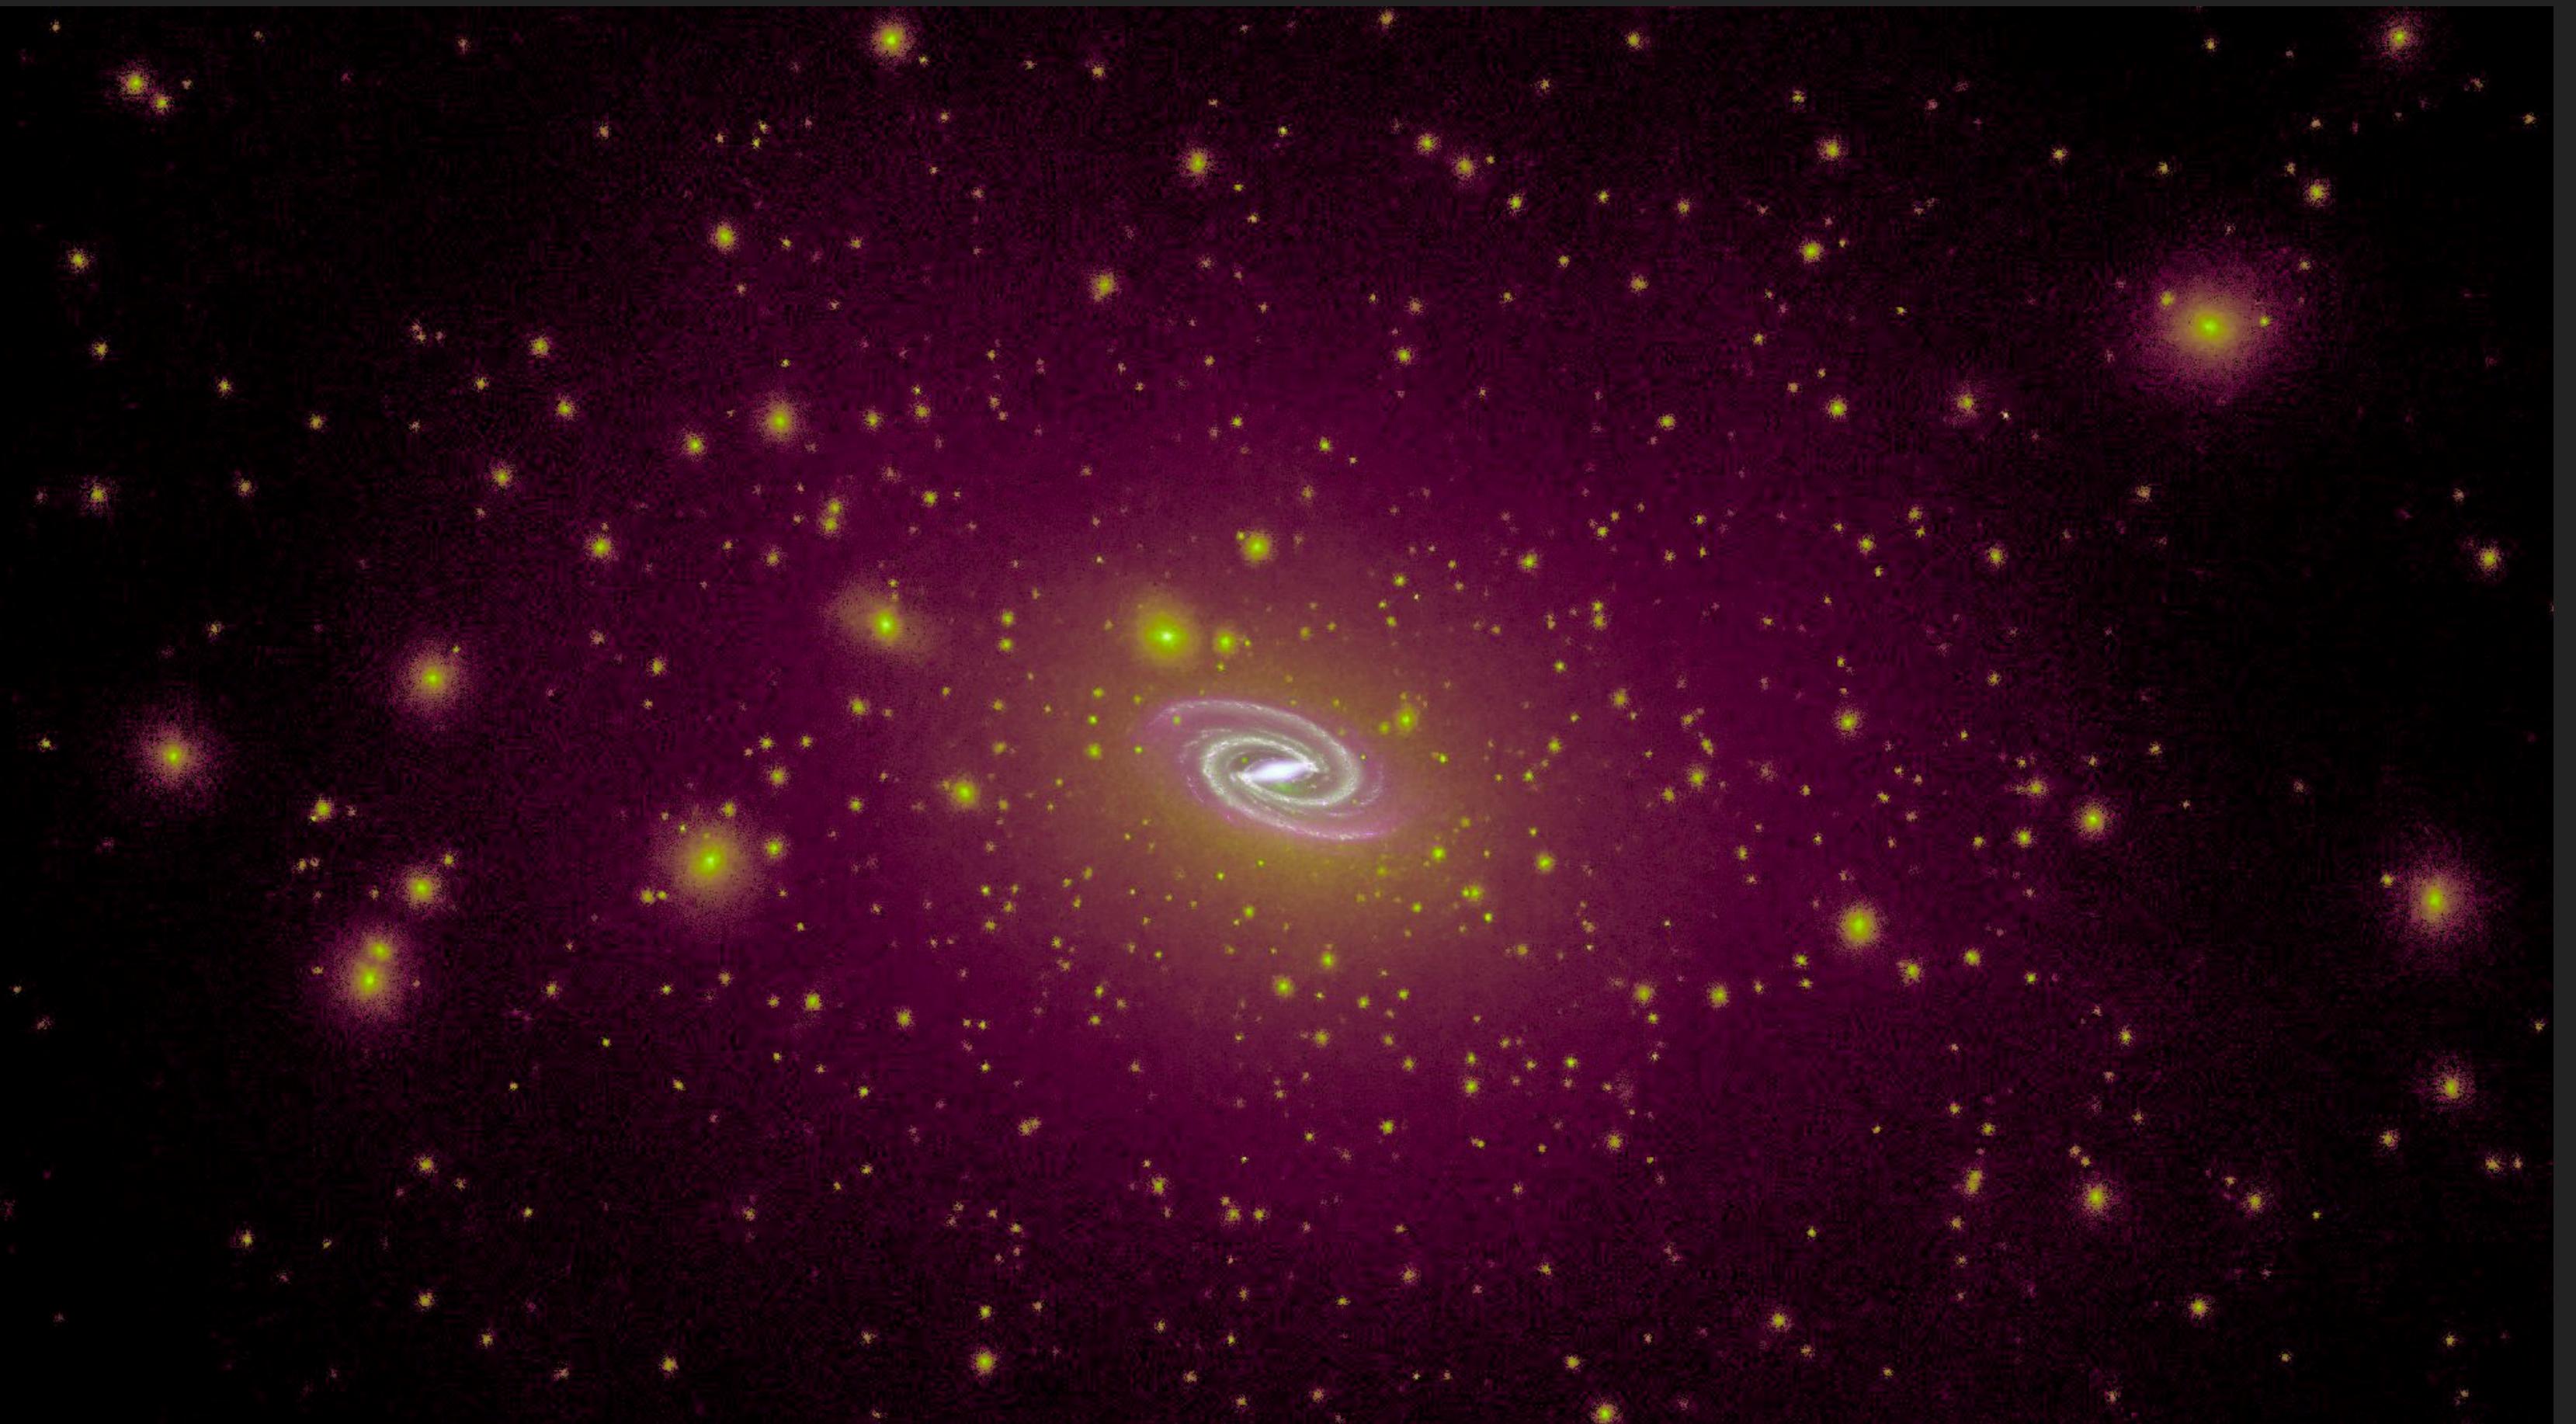

Department of Physics  
UNIVERSITY OF WISCONSIN-MADISON

# INTRODUCTION: MY RESEARCH

## DARK MATTER

- ▶ What we see as a galaxy in space is only a small part of the total mass in that region
- ▶ Invisible “dark matter” envelops galaxies and provides the backbone of structure in the universe
- ▶ Enables formation of galaxies as we know them

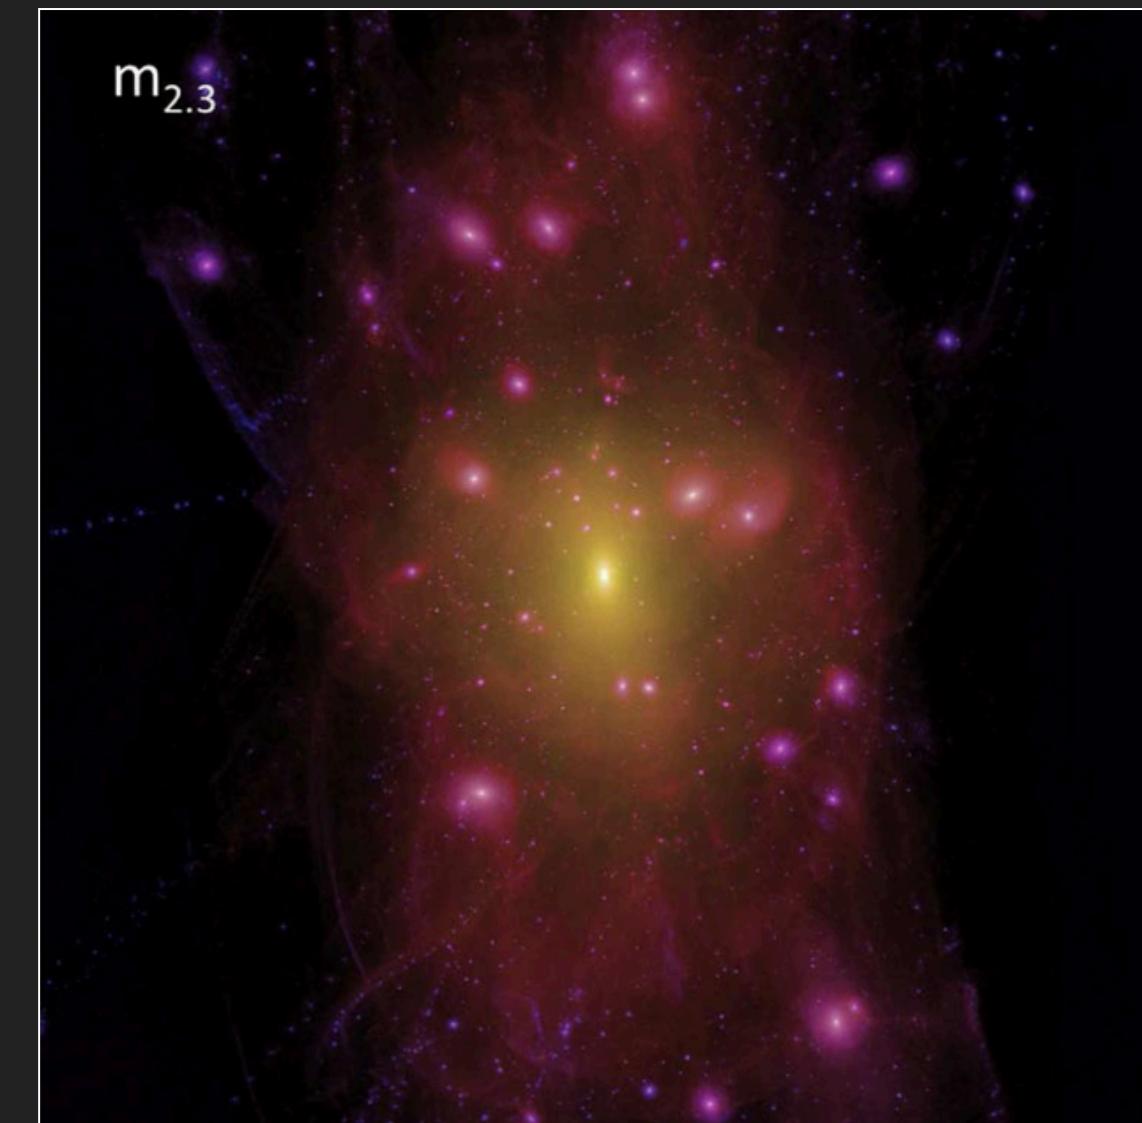

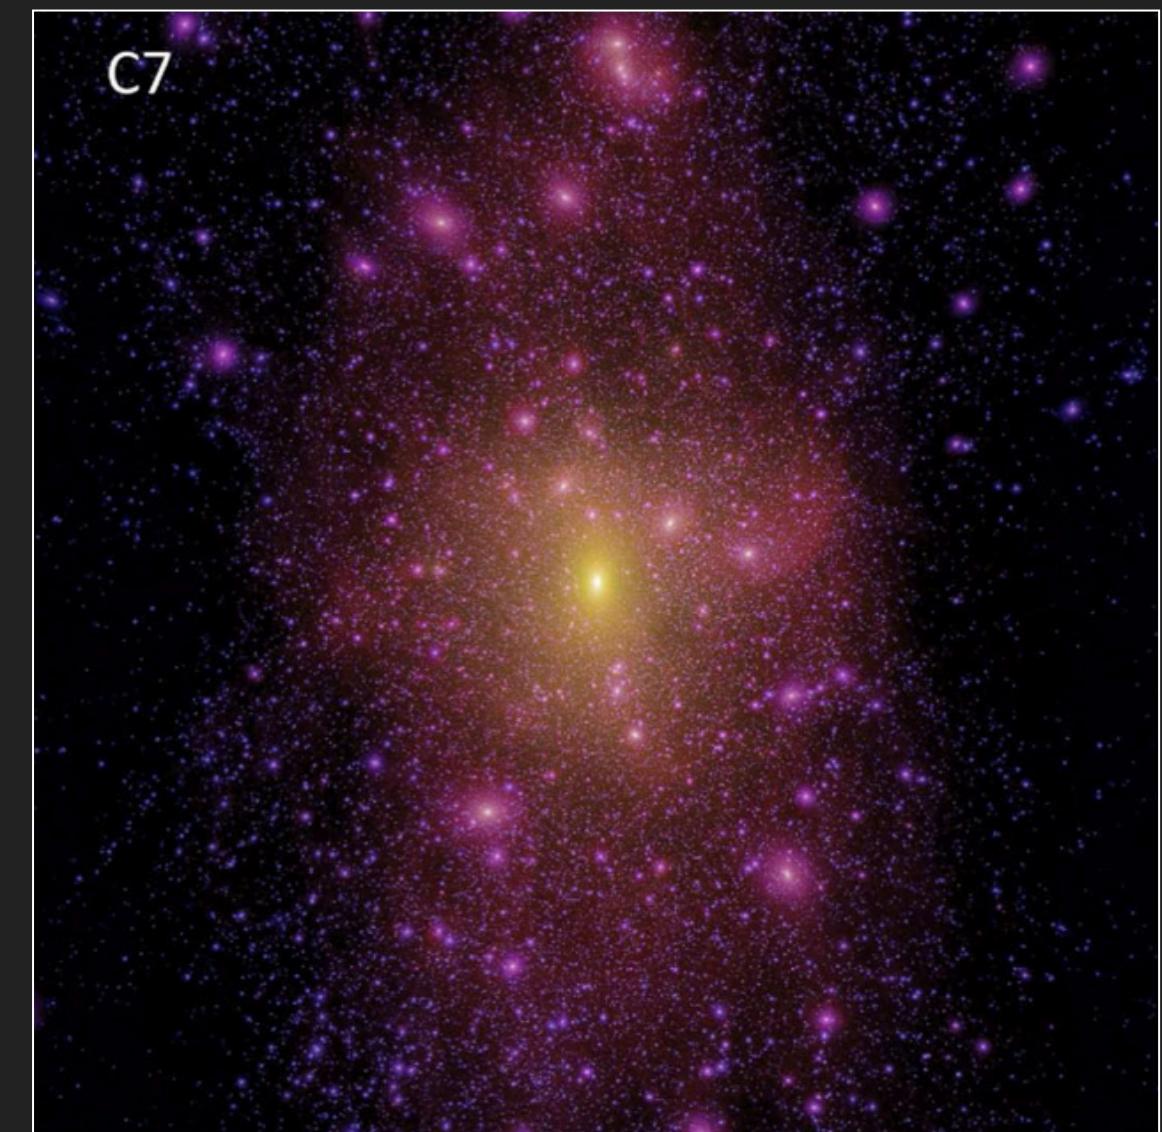

NASA (edited)

# WHAT IS DARK MATTER?

- ▶ 25% of the universe's mass/energy
- ▶ Some massive particle that interacts gravitationally
- ▶ Clumps, or "halos" of dark matter, form the basic structures of the universe
- ▶ The microscopic properties of dark matter affect its macro-scale distribution!
  - ▶ Working from large to small we can learn about particle properties

"Cold Dark Matter":  
Halos form down to  
very small mass  
scales

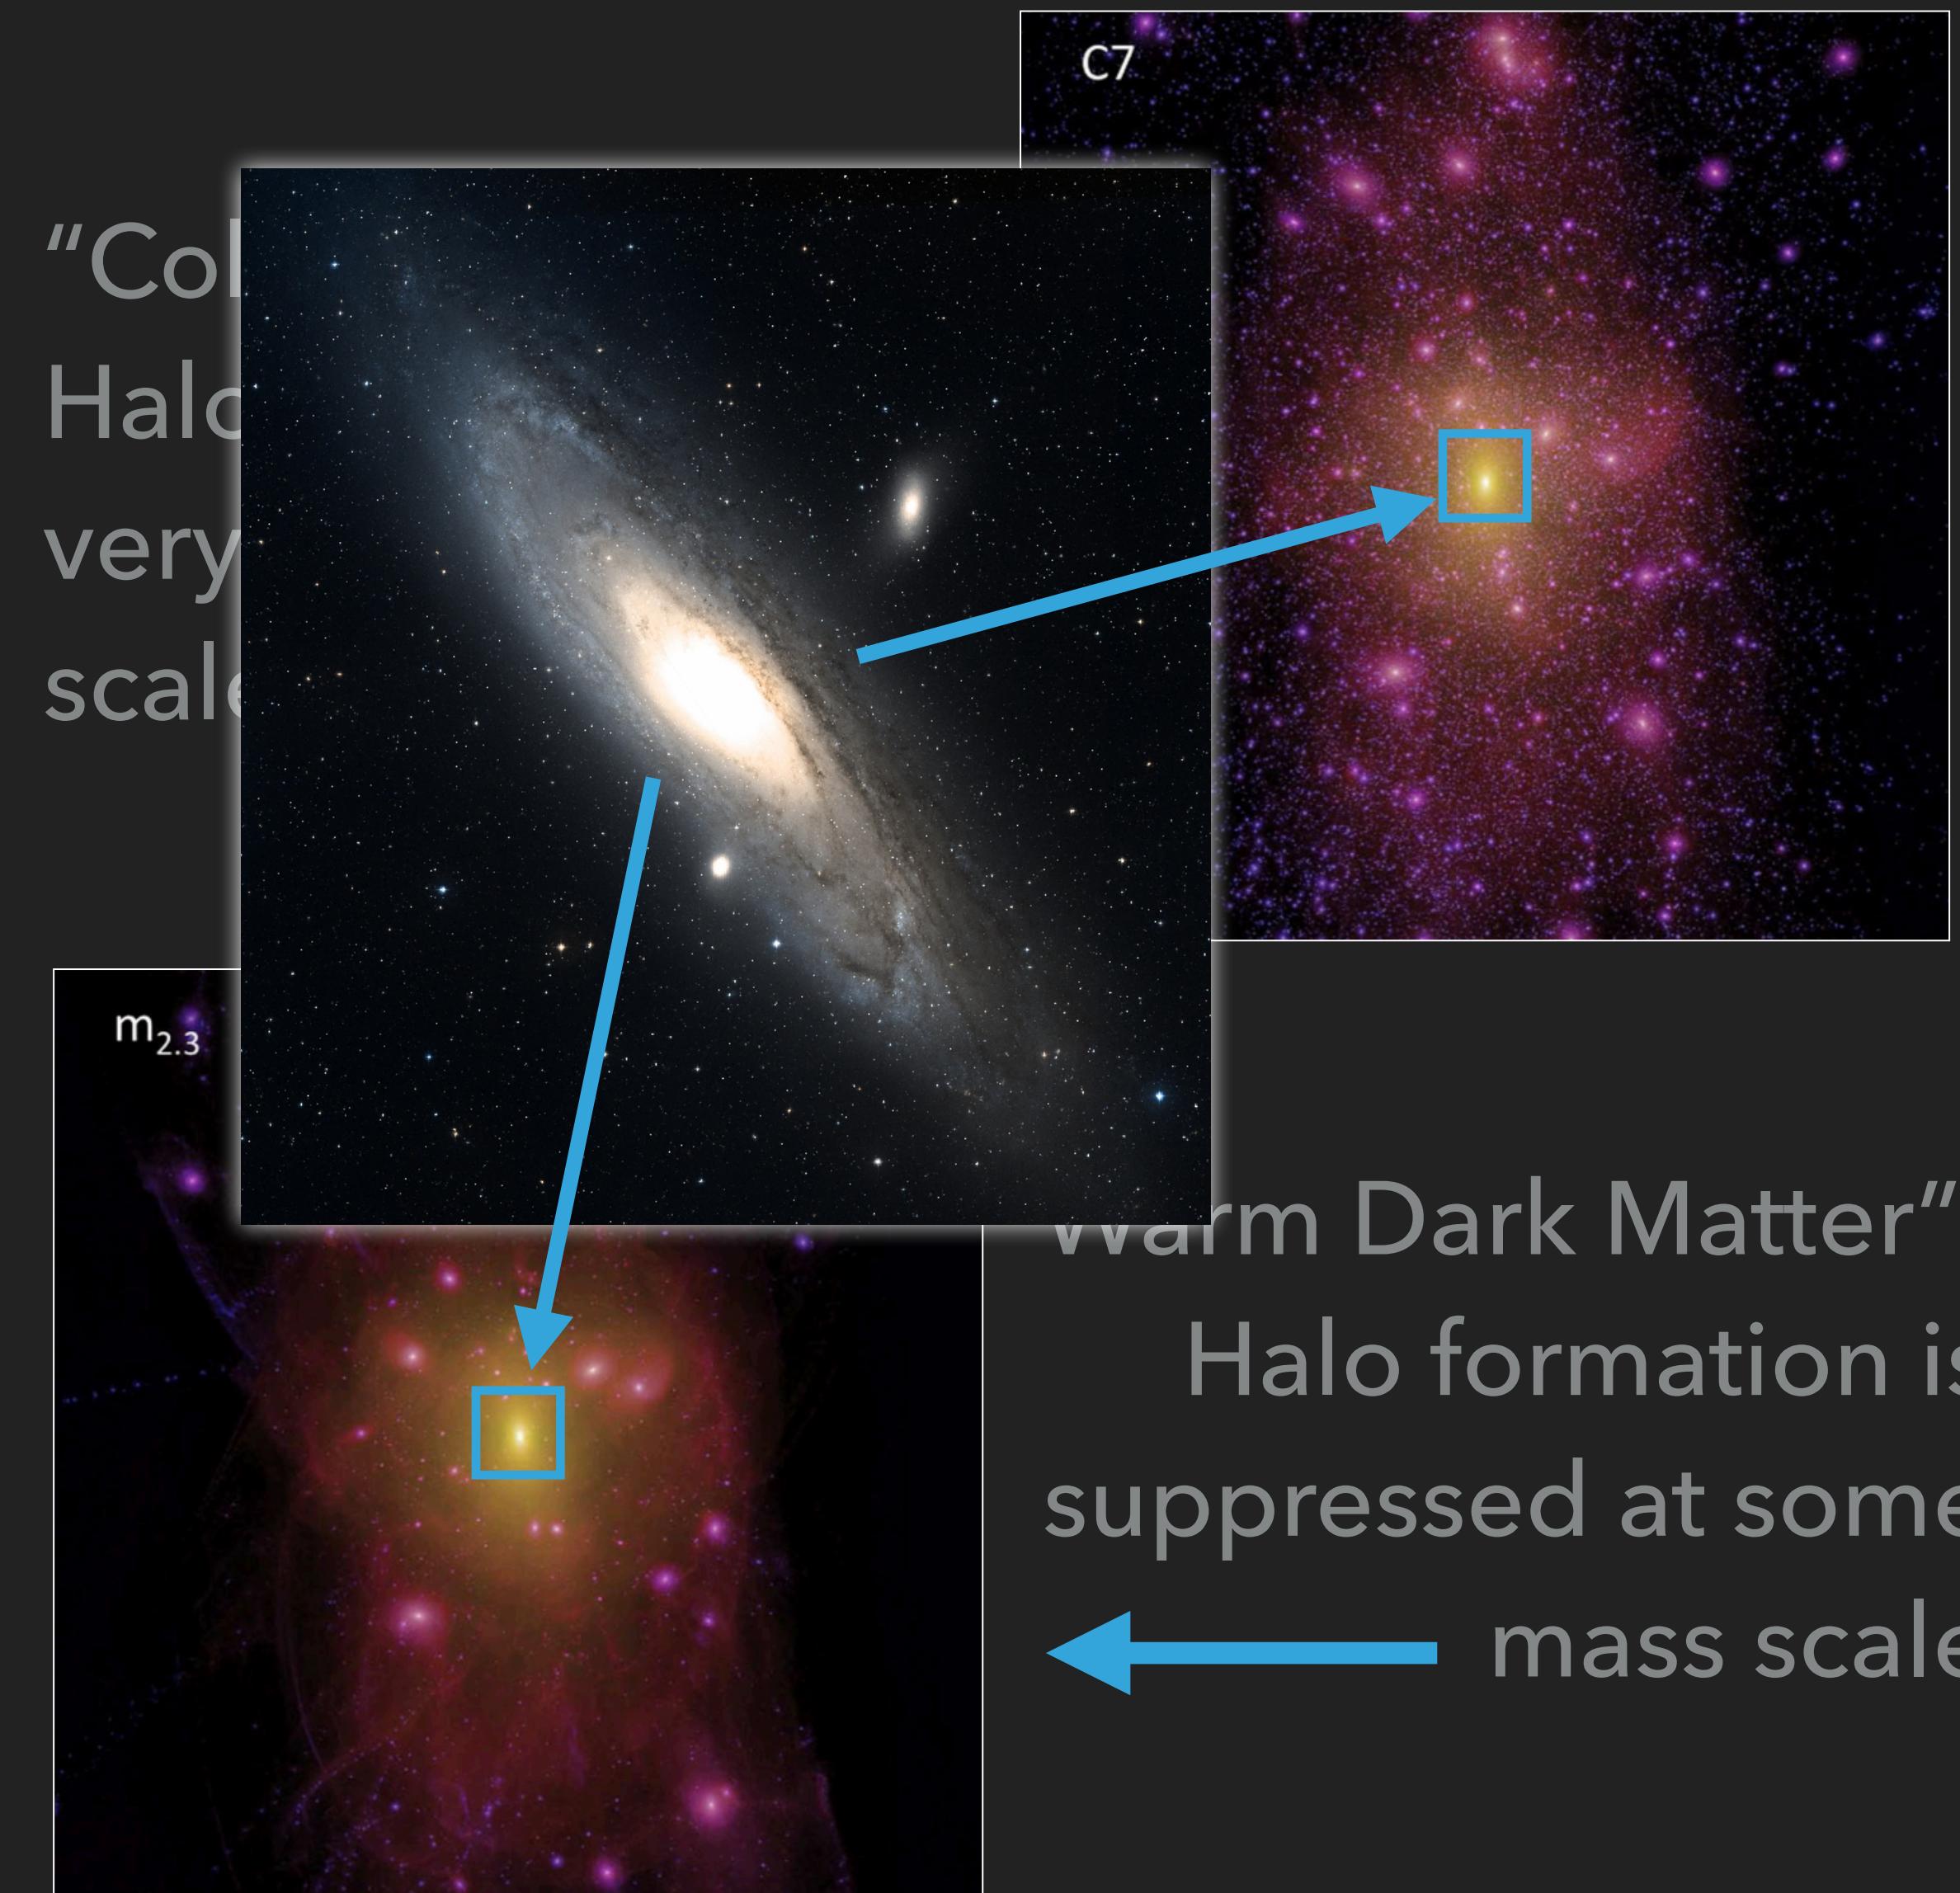

"Warm Dark Matter":  
Halo formation is  
suppressed at some  
mass scale

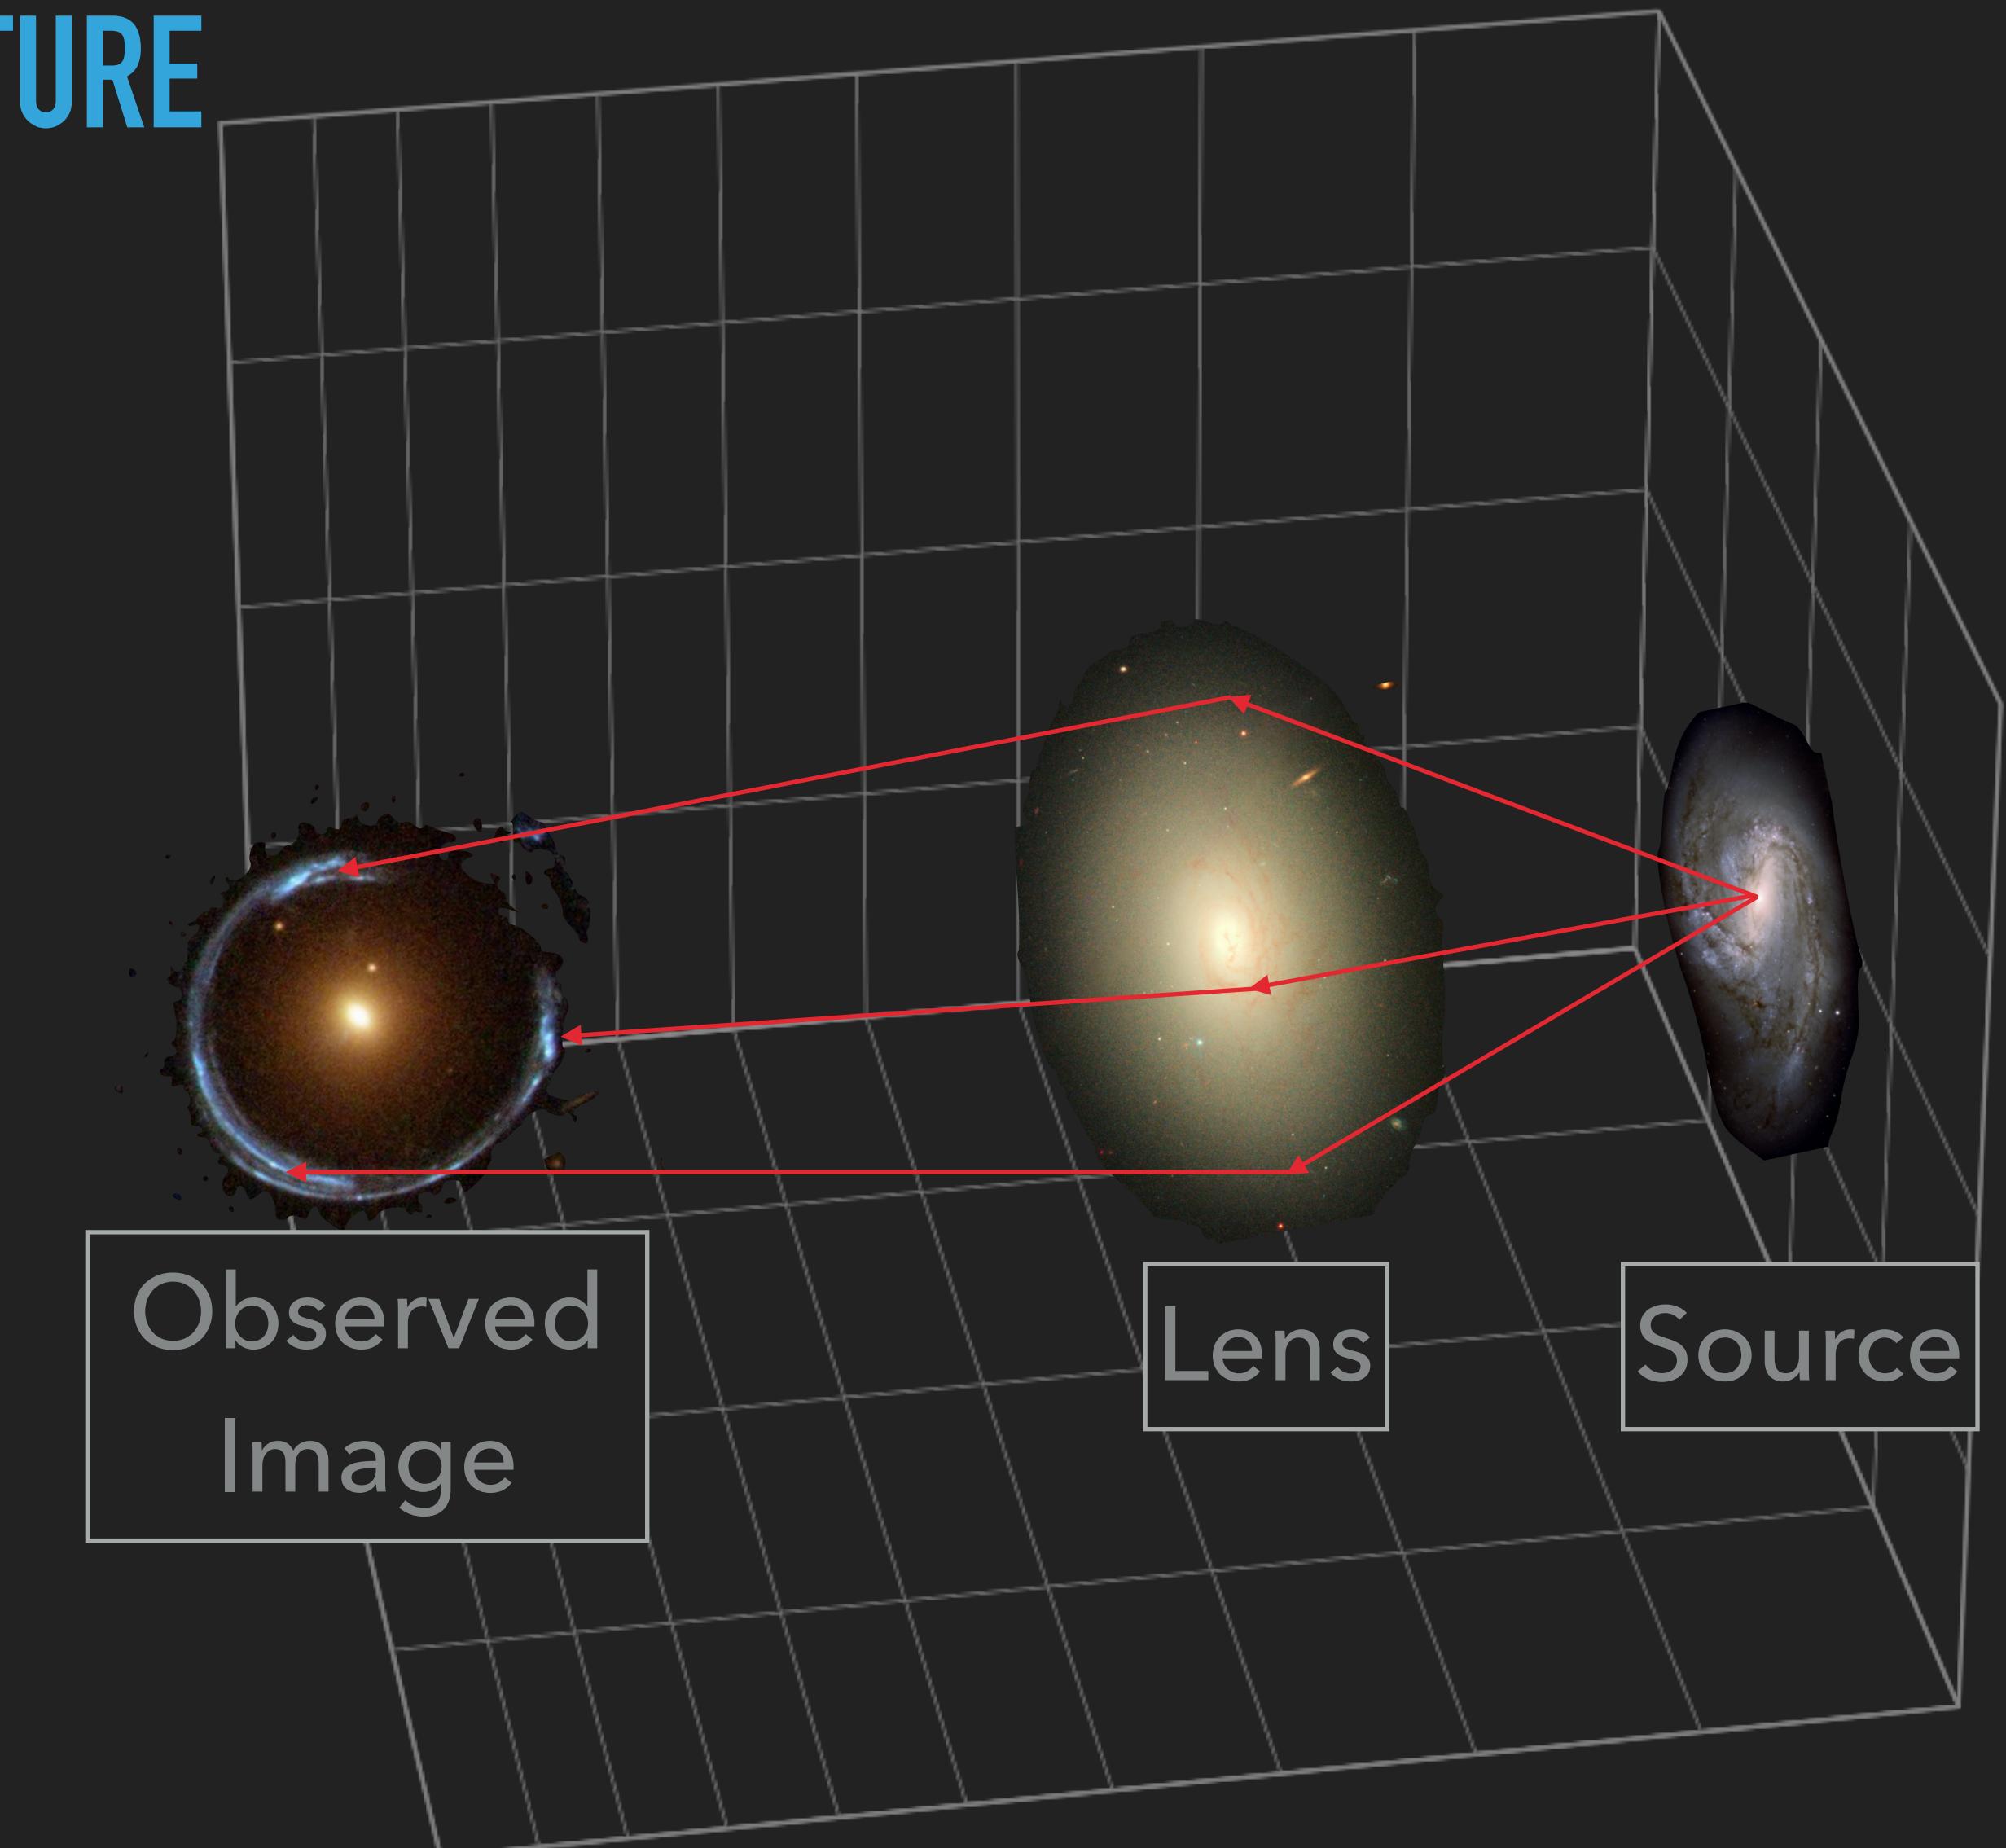

# WHAT IS DARK MATTER?

- ▶ 25% of the universe's mass/energy
- ▶ Some massive particle that interacts gravitationally
- ▶ Clumps, or "halos" of dark matter, form the basic structures of the universe
- ▶ The microscopic properties of dark matter affect its macro-scale distribution!
  - ▶ Working from large to small we can learn about particle properties

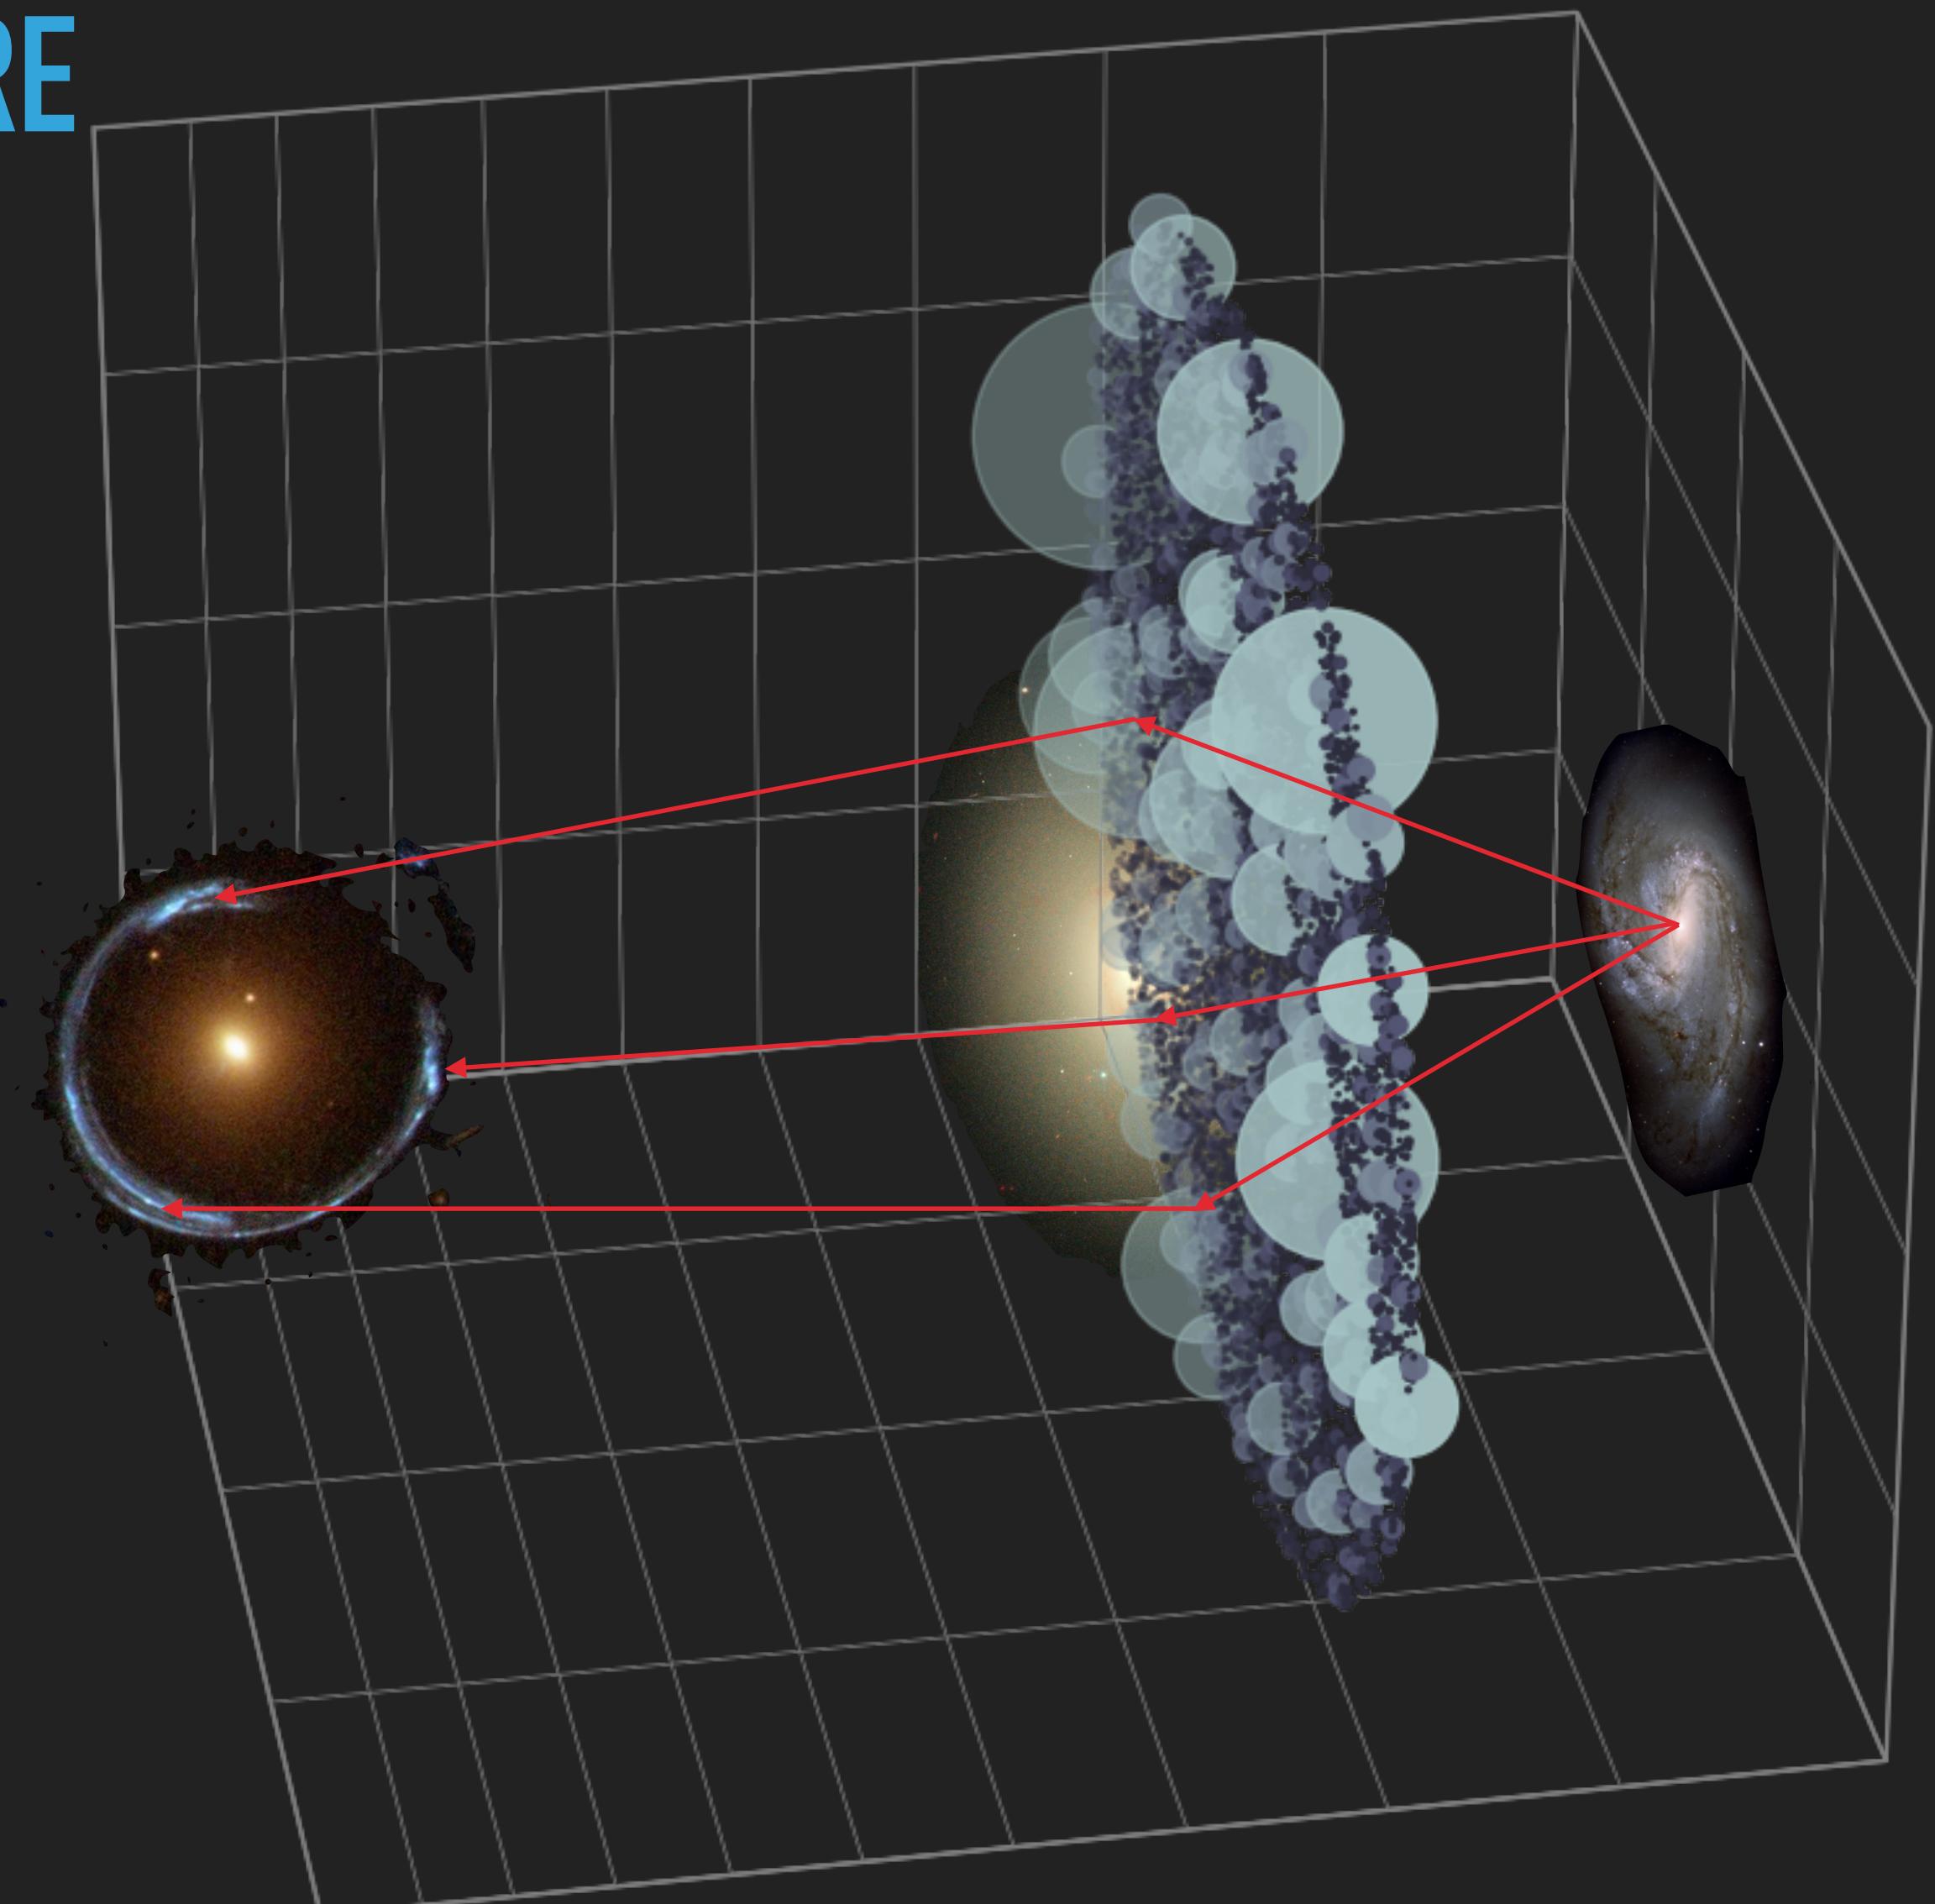

# STRONG LENSING AND DARK SUBSTRUCTURE

- ▶ Massive object splits a background source into multiple observed images
- ▶ Distortion of extended sources produces arc shapes around the lens
- ▶ “Cosmic telescope” with many applications

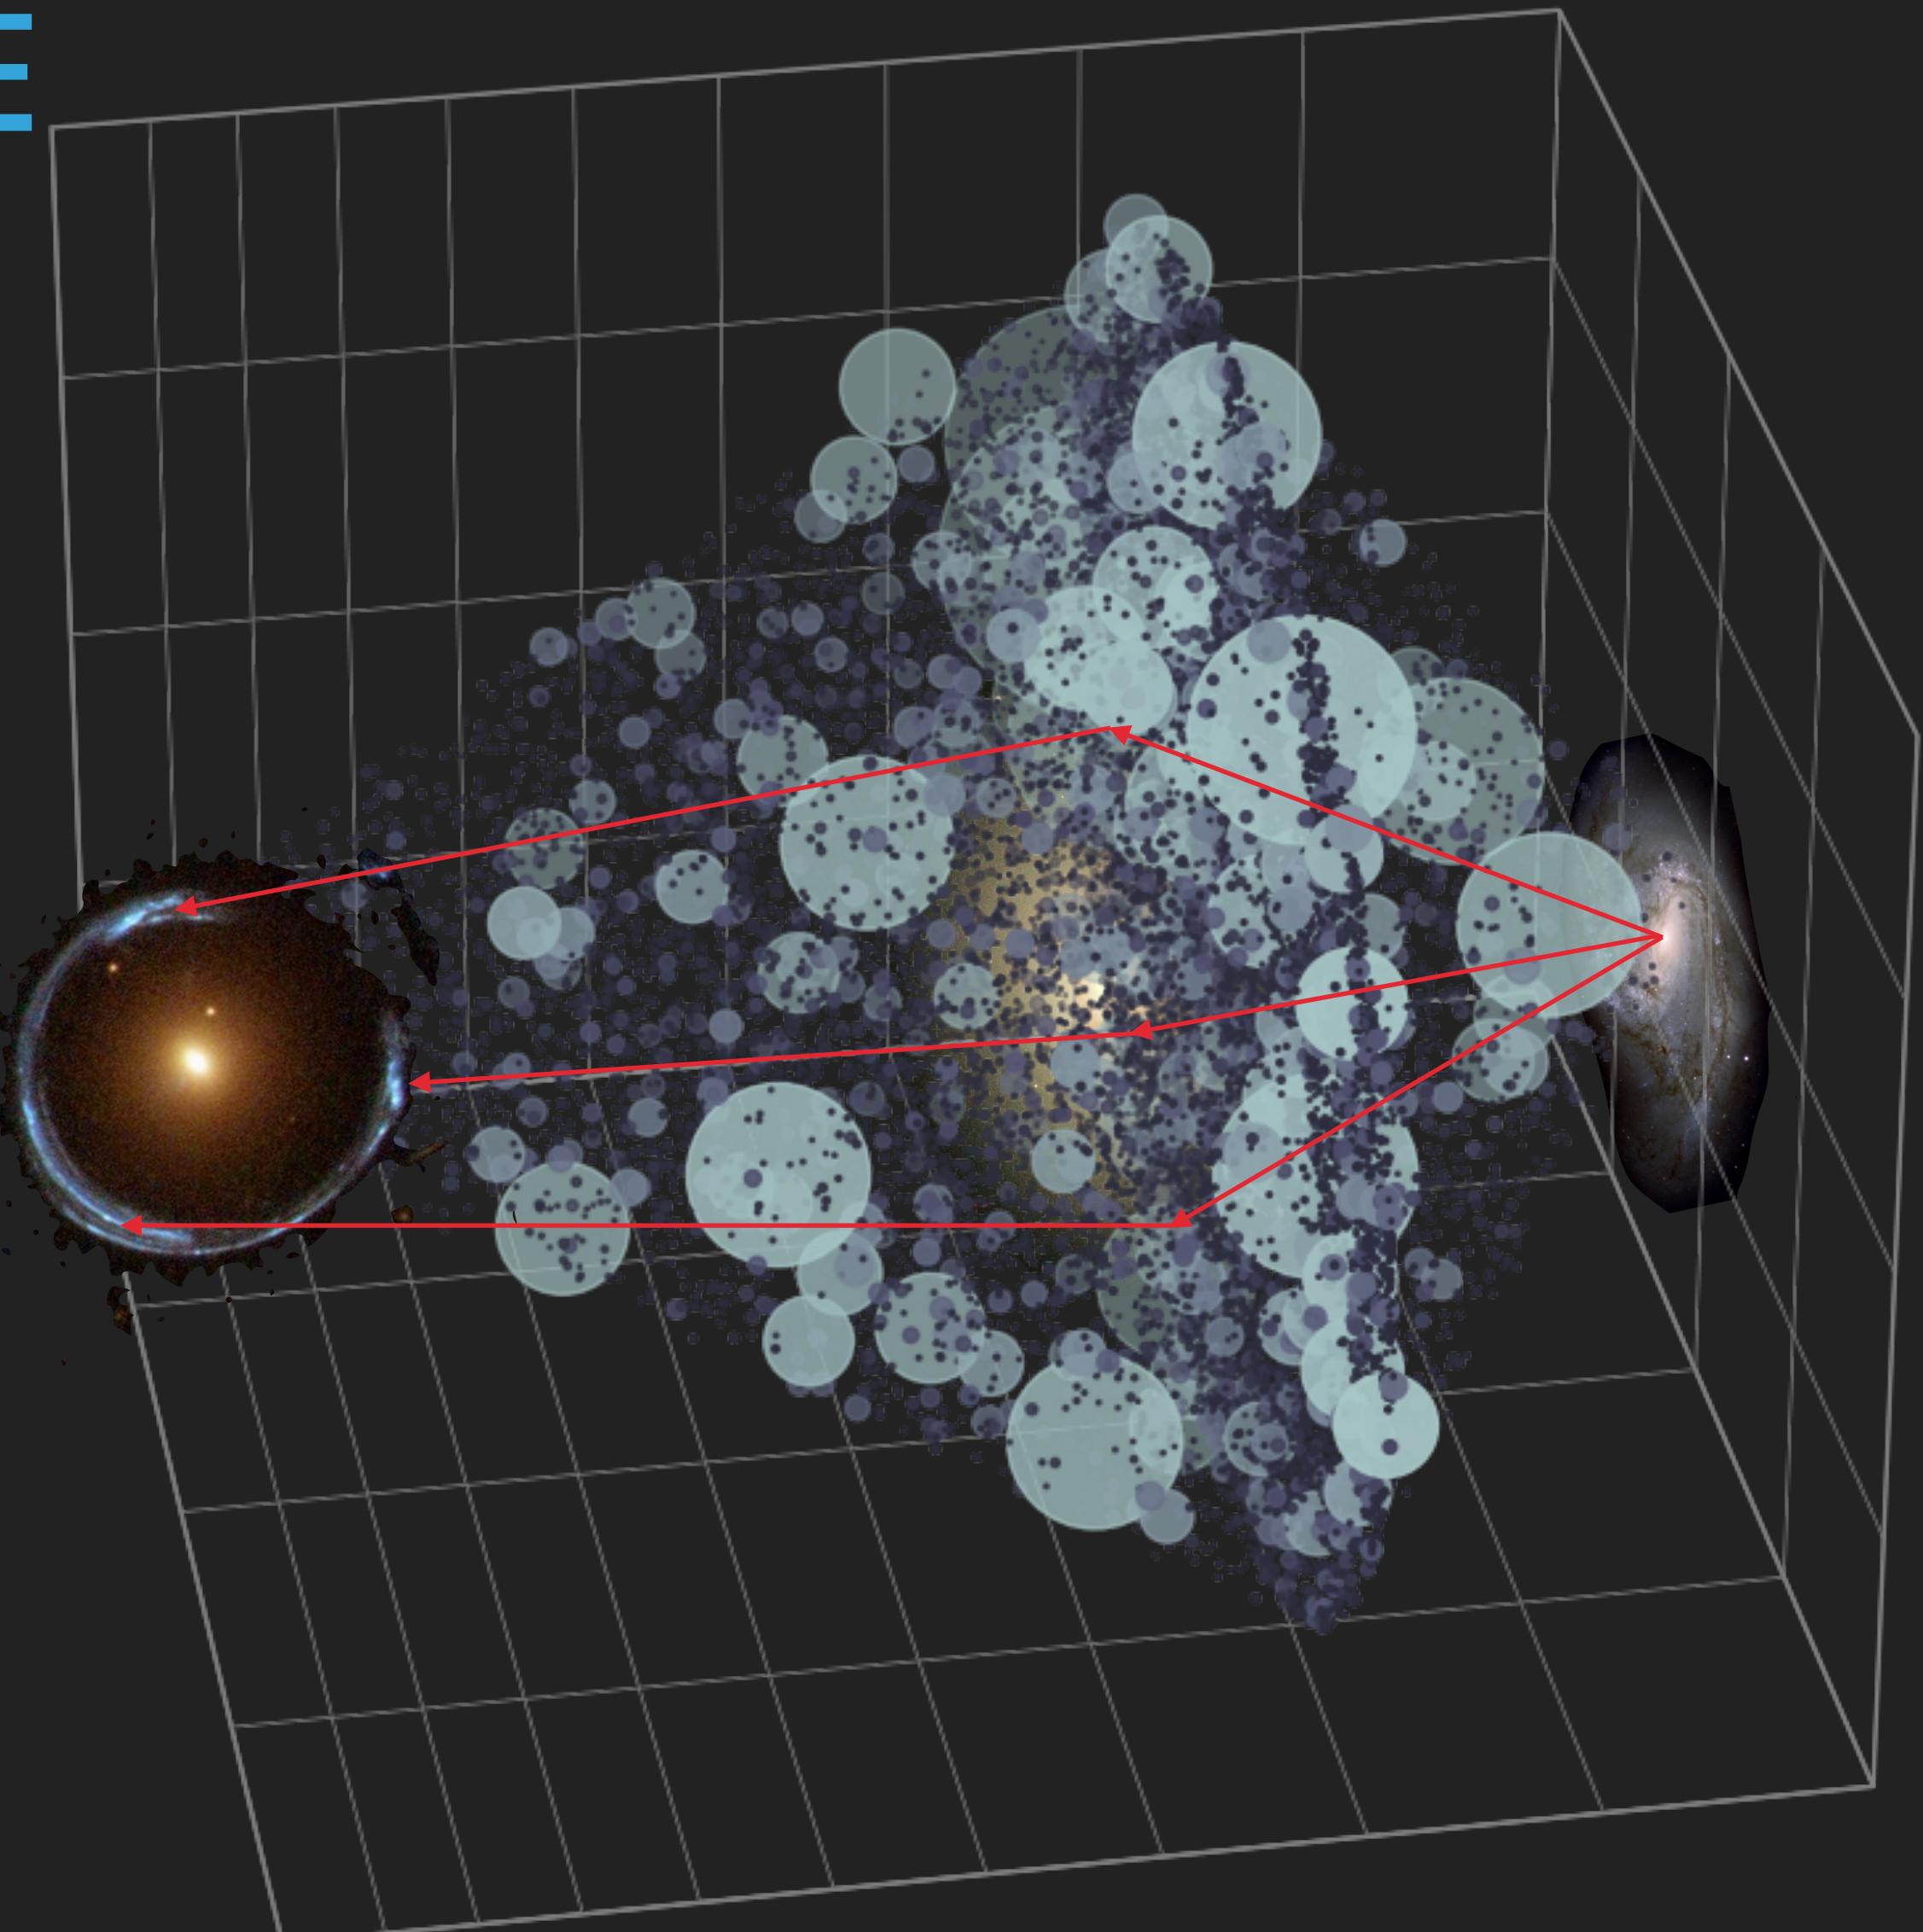

## STRONG LENSING AND DARK SUBSTRUCTURE

- ▶ The lensing effect is sensitive to *all* mass along the light's path
- ▶ Smaller dark matter halos can affect image positions, brightness, etc
- ▶ These halos are typically too small to form stars, making them invisible

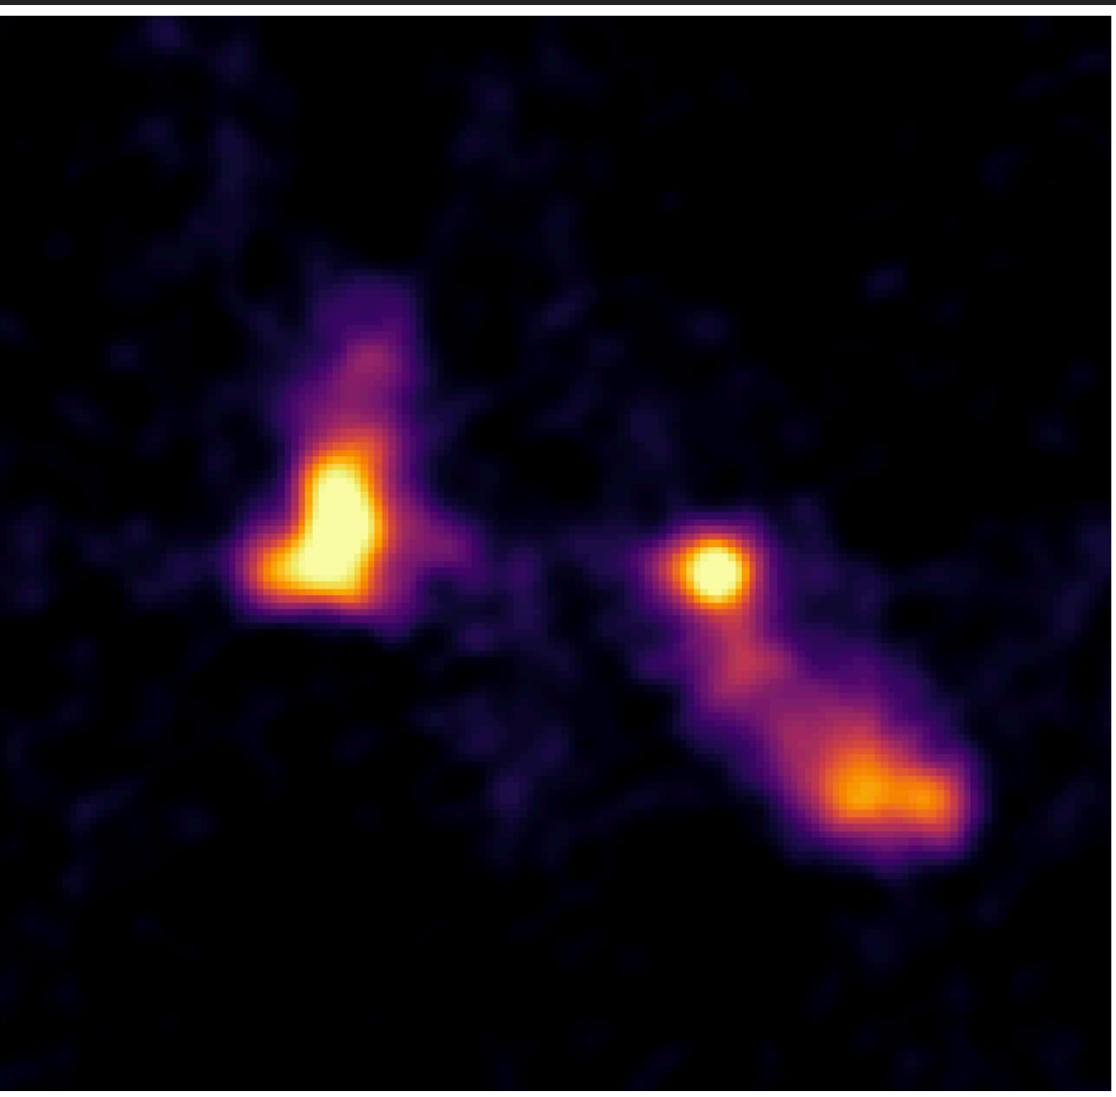

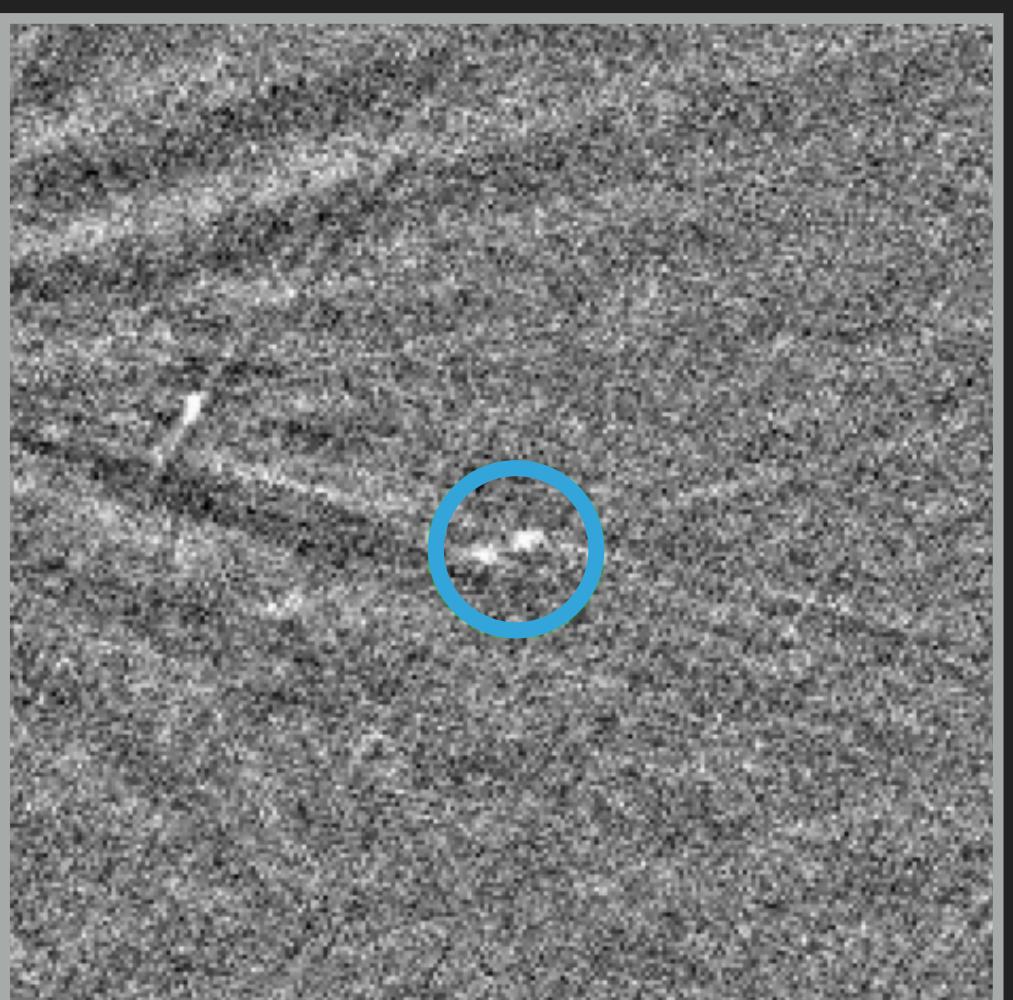

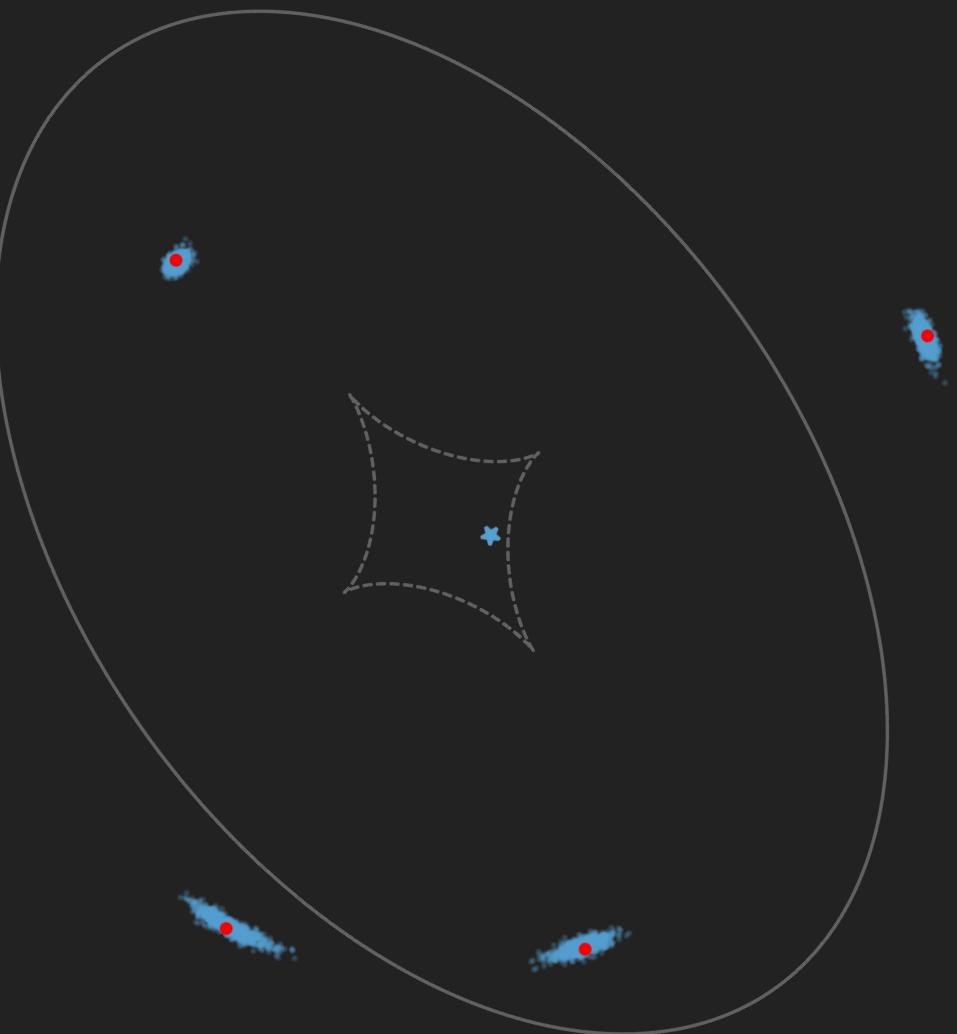

## STRONG LENSING AND DARK SUBSTRUCTURE

- ▶ The lensing effect is sensitive to *all* mass along the light's path
- ▶ Smaller dark matter halos can affect image positions, brightness, etc
- ▶ These halos are typically too small to form stars, making them invisible
- ▶ Other halos unaffiliated with the main lens also contribute!

## COMPUTATION IN MY RESEARCH

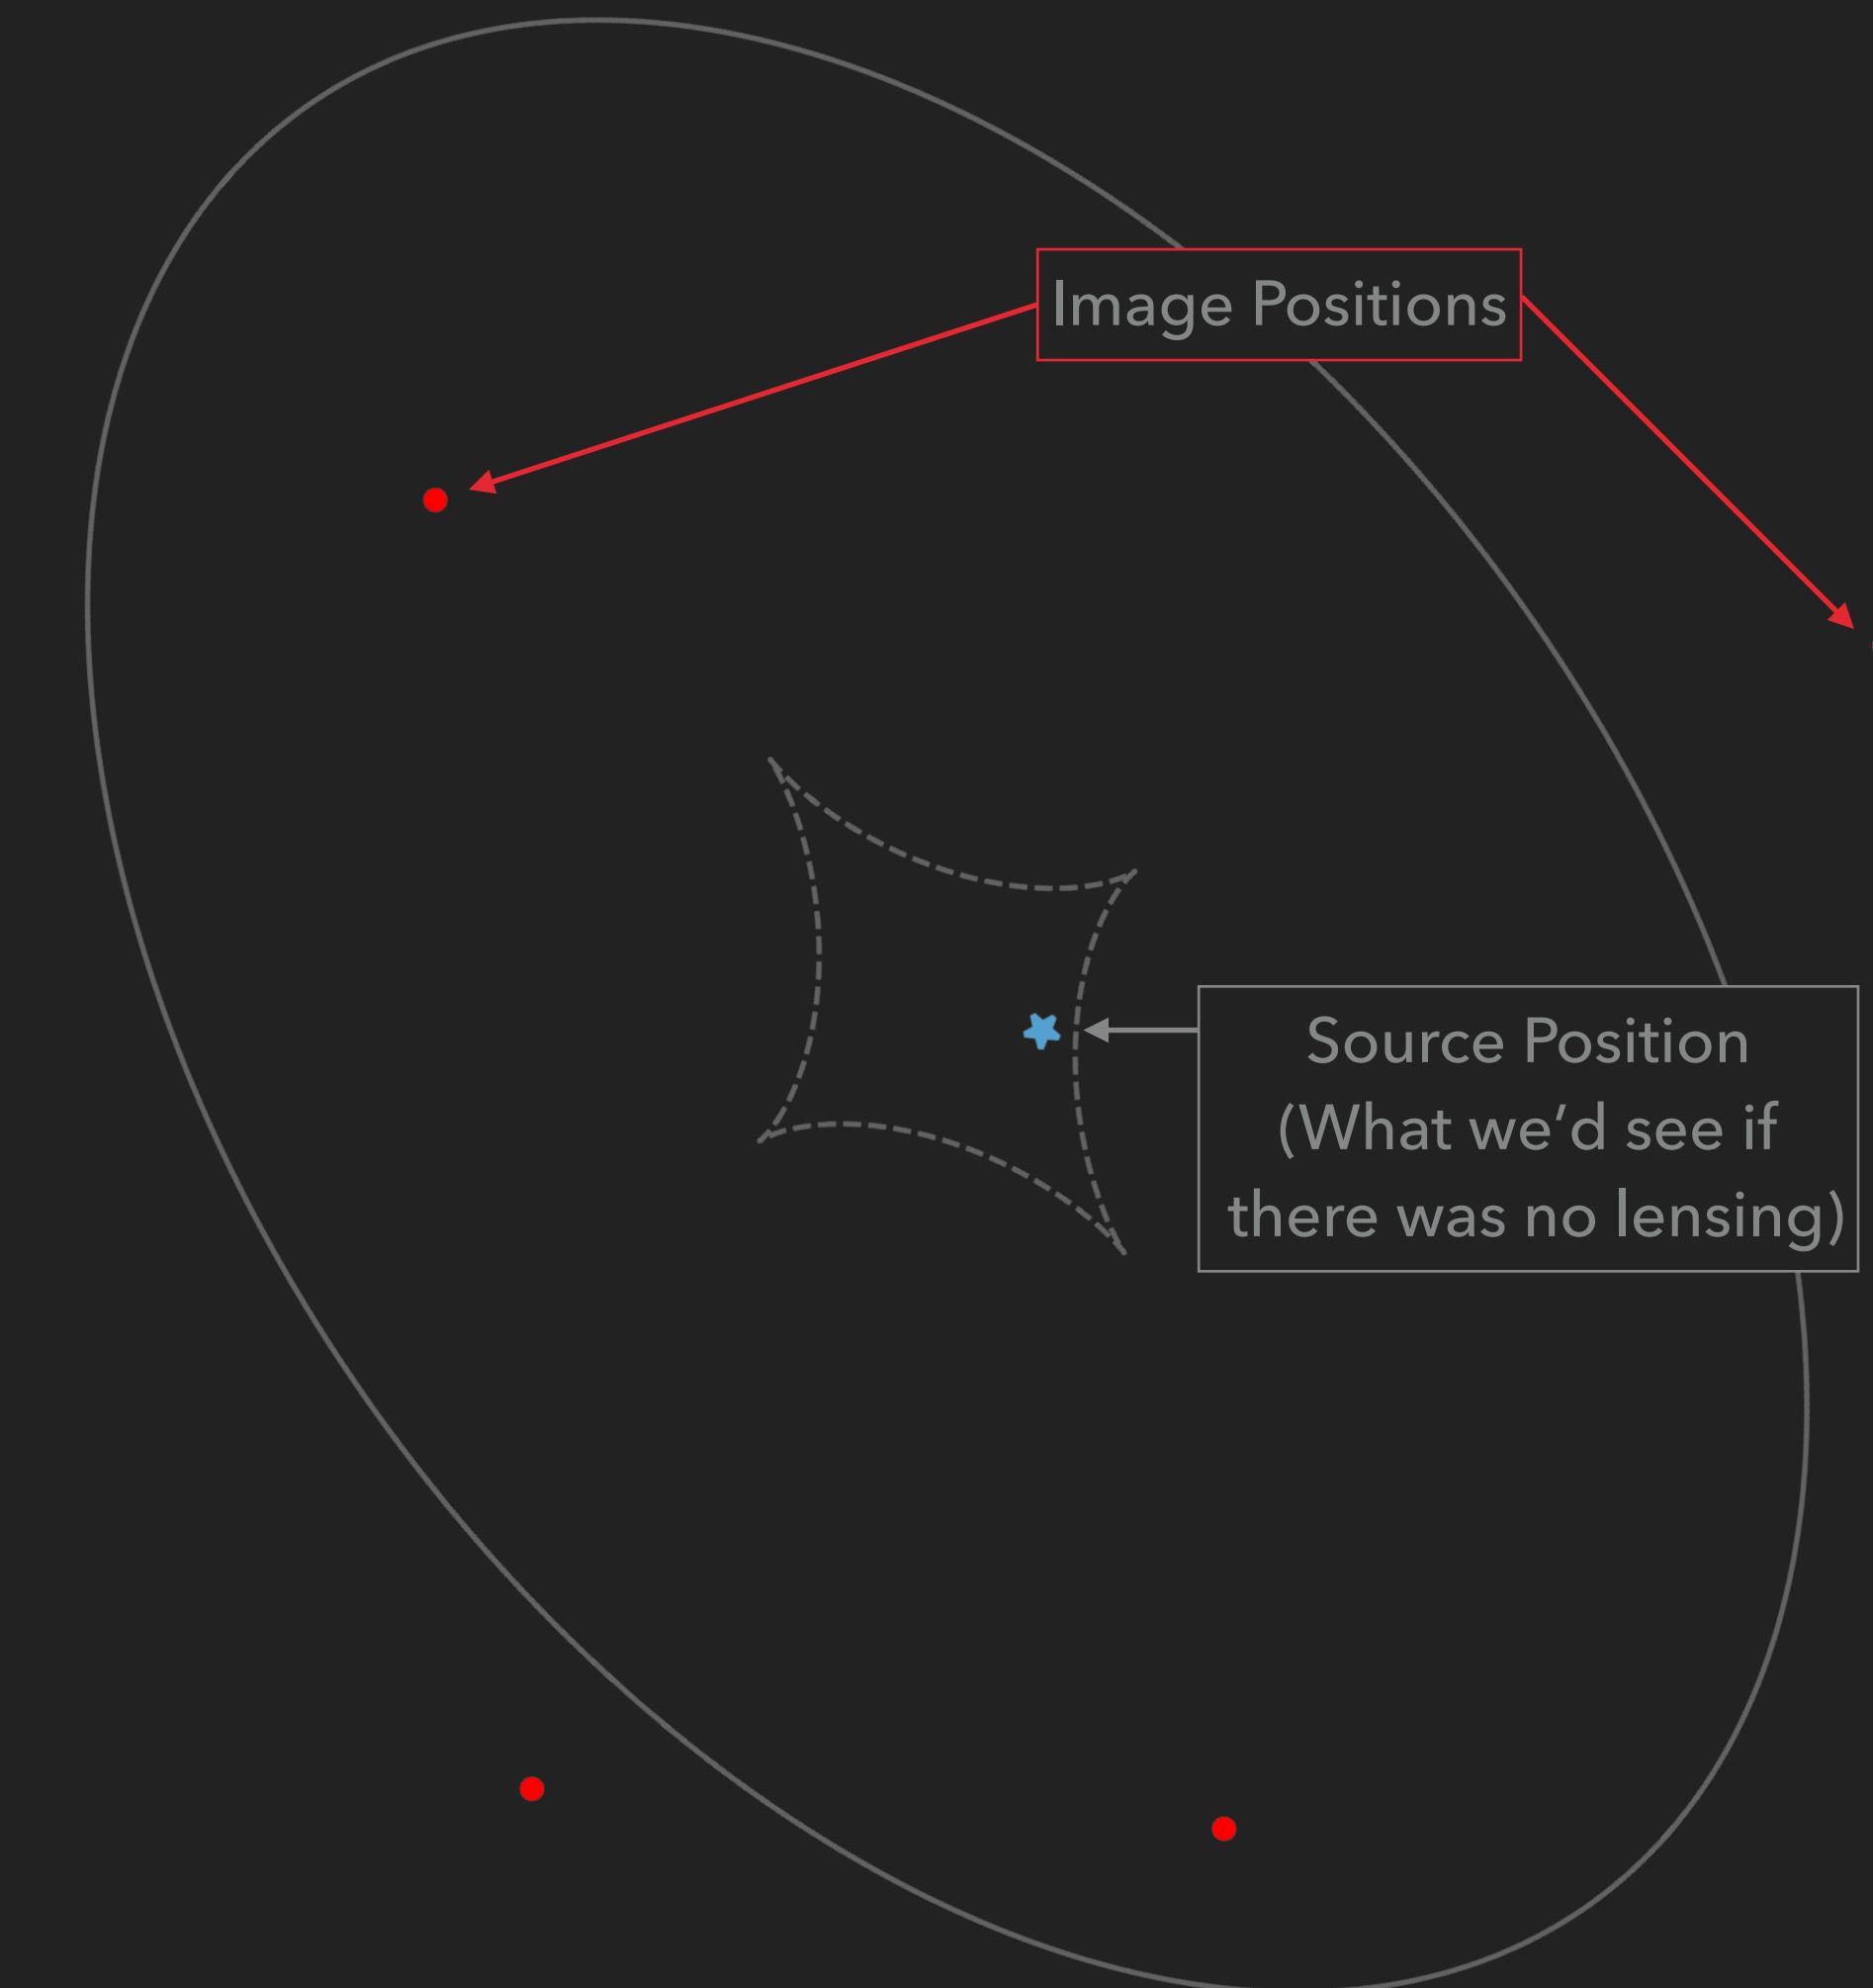

- ▶ Simulations: How do lenses look given different models of dark matter?
- ▶ Radio imaging: Processing data from real gravitational lenses
- ▶ Image stacking: Finding more lenses by increasing sensitivity of a radio survey

# PROJECT 1: DARK MATTER SIMULATIONS

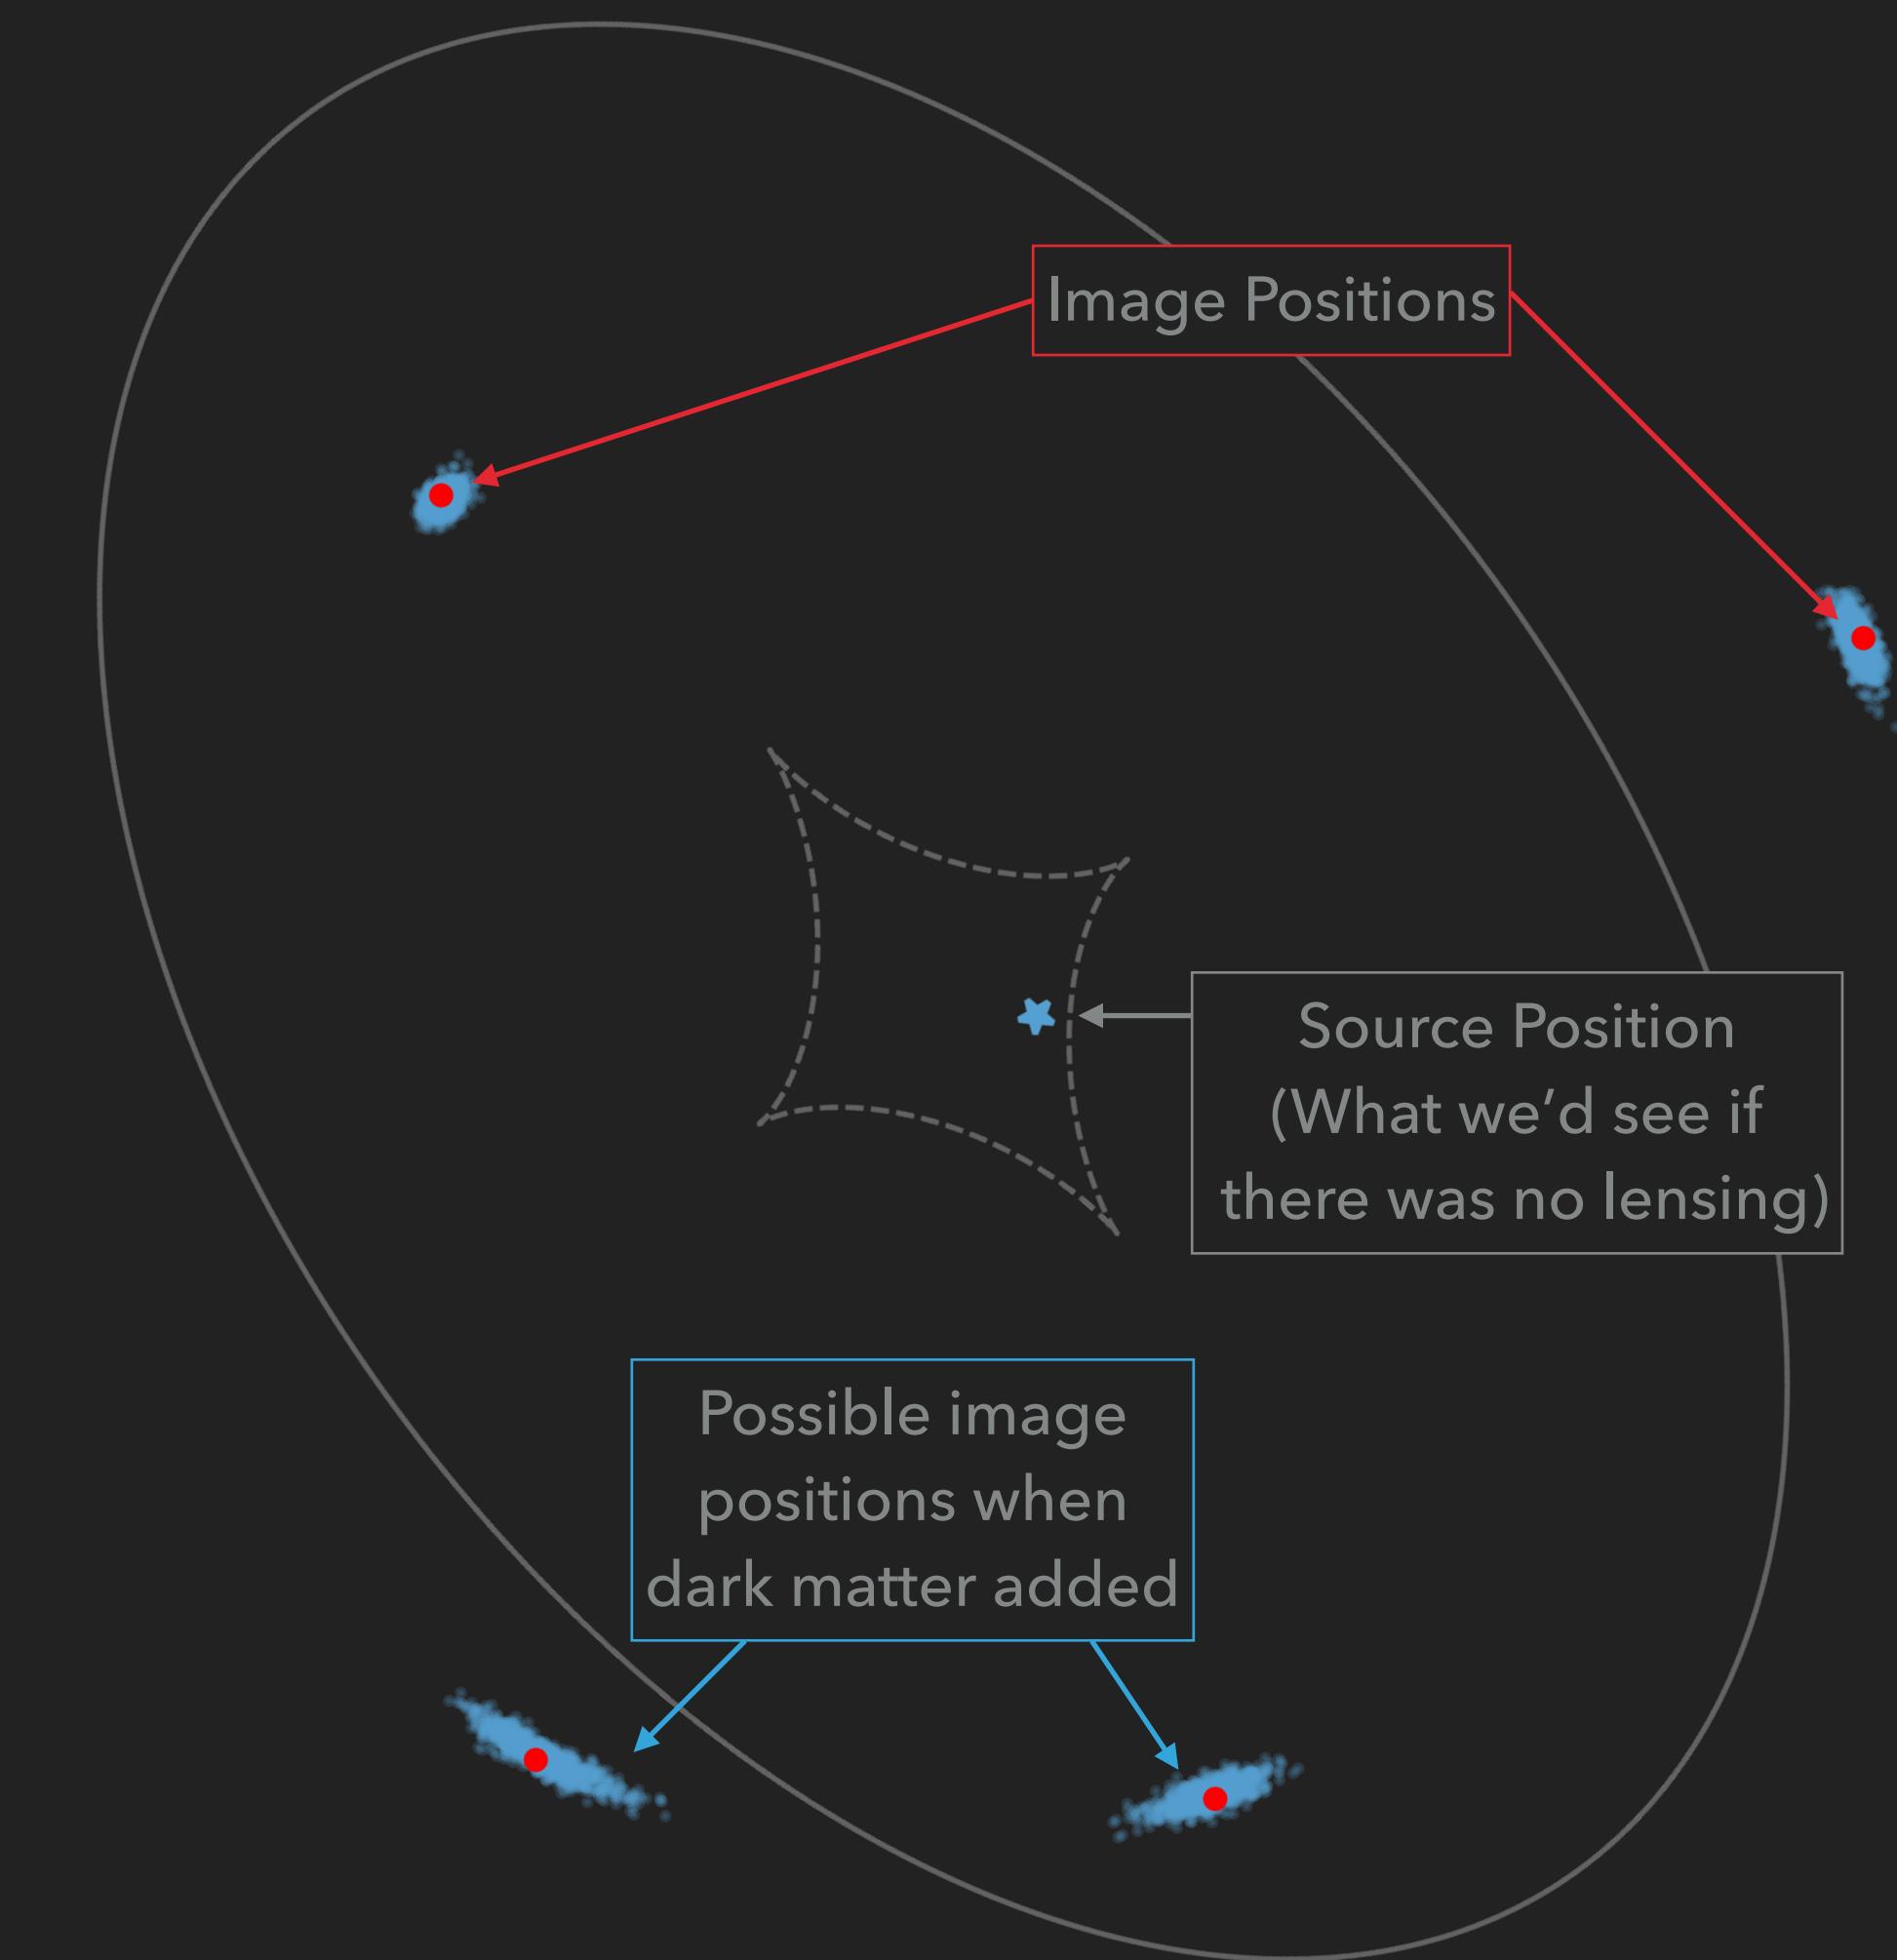

## SIMULATING DARK SUBSTRUCTURE ON CHTC

- ▶ Goal: Study how different models of dark matter affect image positions
- ▶ Many dark matter halos → simulating lensing takes a long time!
- ▶ Enter CHTC: Many simulations at once, with different model parameters
- ▶ Red points: image positions for a lens with no dark matter substructure

## SIMULATING DARK SUBSTRUCTURE ON CHTC

- ▶ Goal: Study how different models of dark matter affect image positions
- ▶ Many dark matter halos → simulating lensing takes a long time!
- ▶ Enter CHTC: Many simulations at once, with different model parameters
- ▶ Blue cloud: image positions for 1000 full substructure simulations

## MOVING TO CHTC

- ▶ Very natural task for high-throughput computing
- ▶ Python Apptainer image with needed packages
- ▶ Each job does its own set of simulations, I collect them after
- ▶ ~2 days start to finish, computing took under an hour

```
#Apptainer image
Bootstrap: docker
From: python:3.11

%post
    python3 -m pip install numpy scipy==1.13.1 astropy
              matplotlib lenstronomy==1.11.10 colossus
              mcfit pyhalo==1.2
```

```
#Condor Submission File
container_image = file:///staging/mnmartinez/image.sif
executable = script.py
arguments = $(Cluster)_$(Process)
should_transfer_files = YES
when_to_transfer_output = ON_EXIT_OR_EVICT

log = job_$(Cluster)_$(Process).log
error = job_$(Cluster)_$(Process).err
output = job_$(Cluster)_$(Process).out

requirements = (HasCHTCStaging == true)
request_cpus = 1
request_memory = 2GB
request_disk = 1GB

queue 50
```

# PROJECT 2: RADIO INTERFEROMETRY

## RADIO INTERFEROMETRY

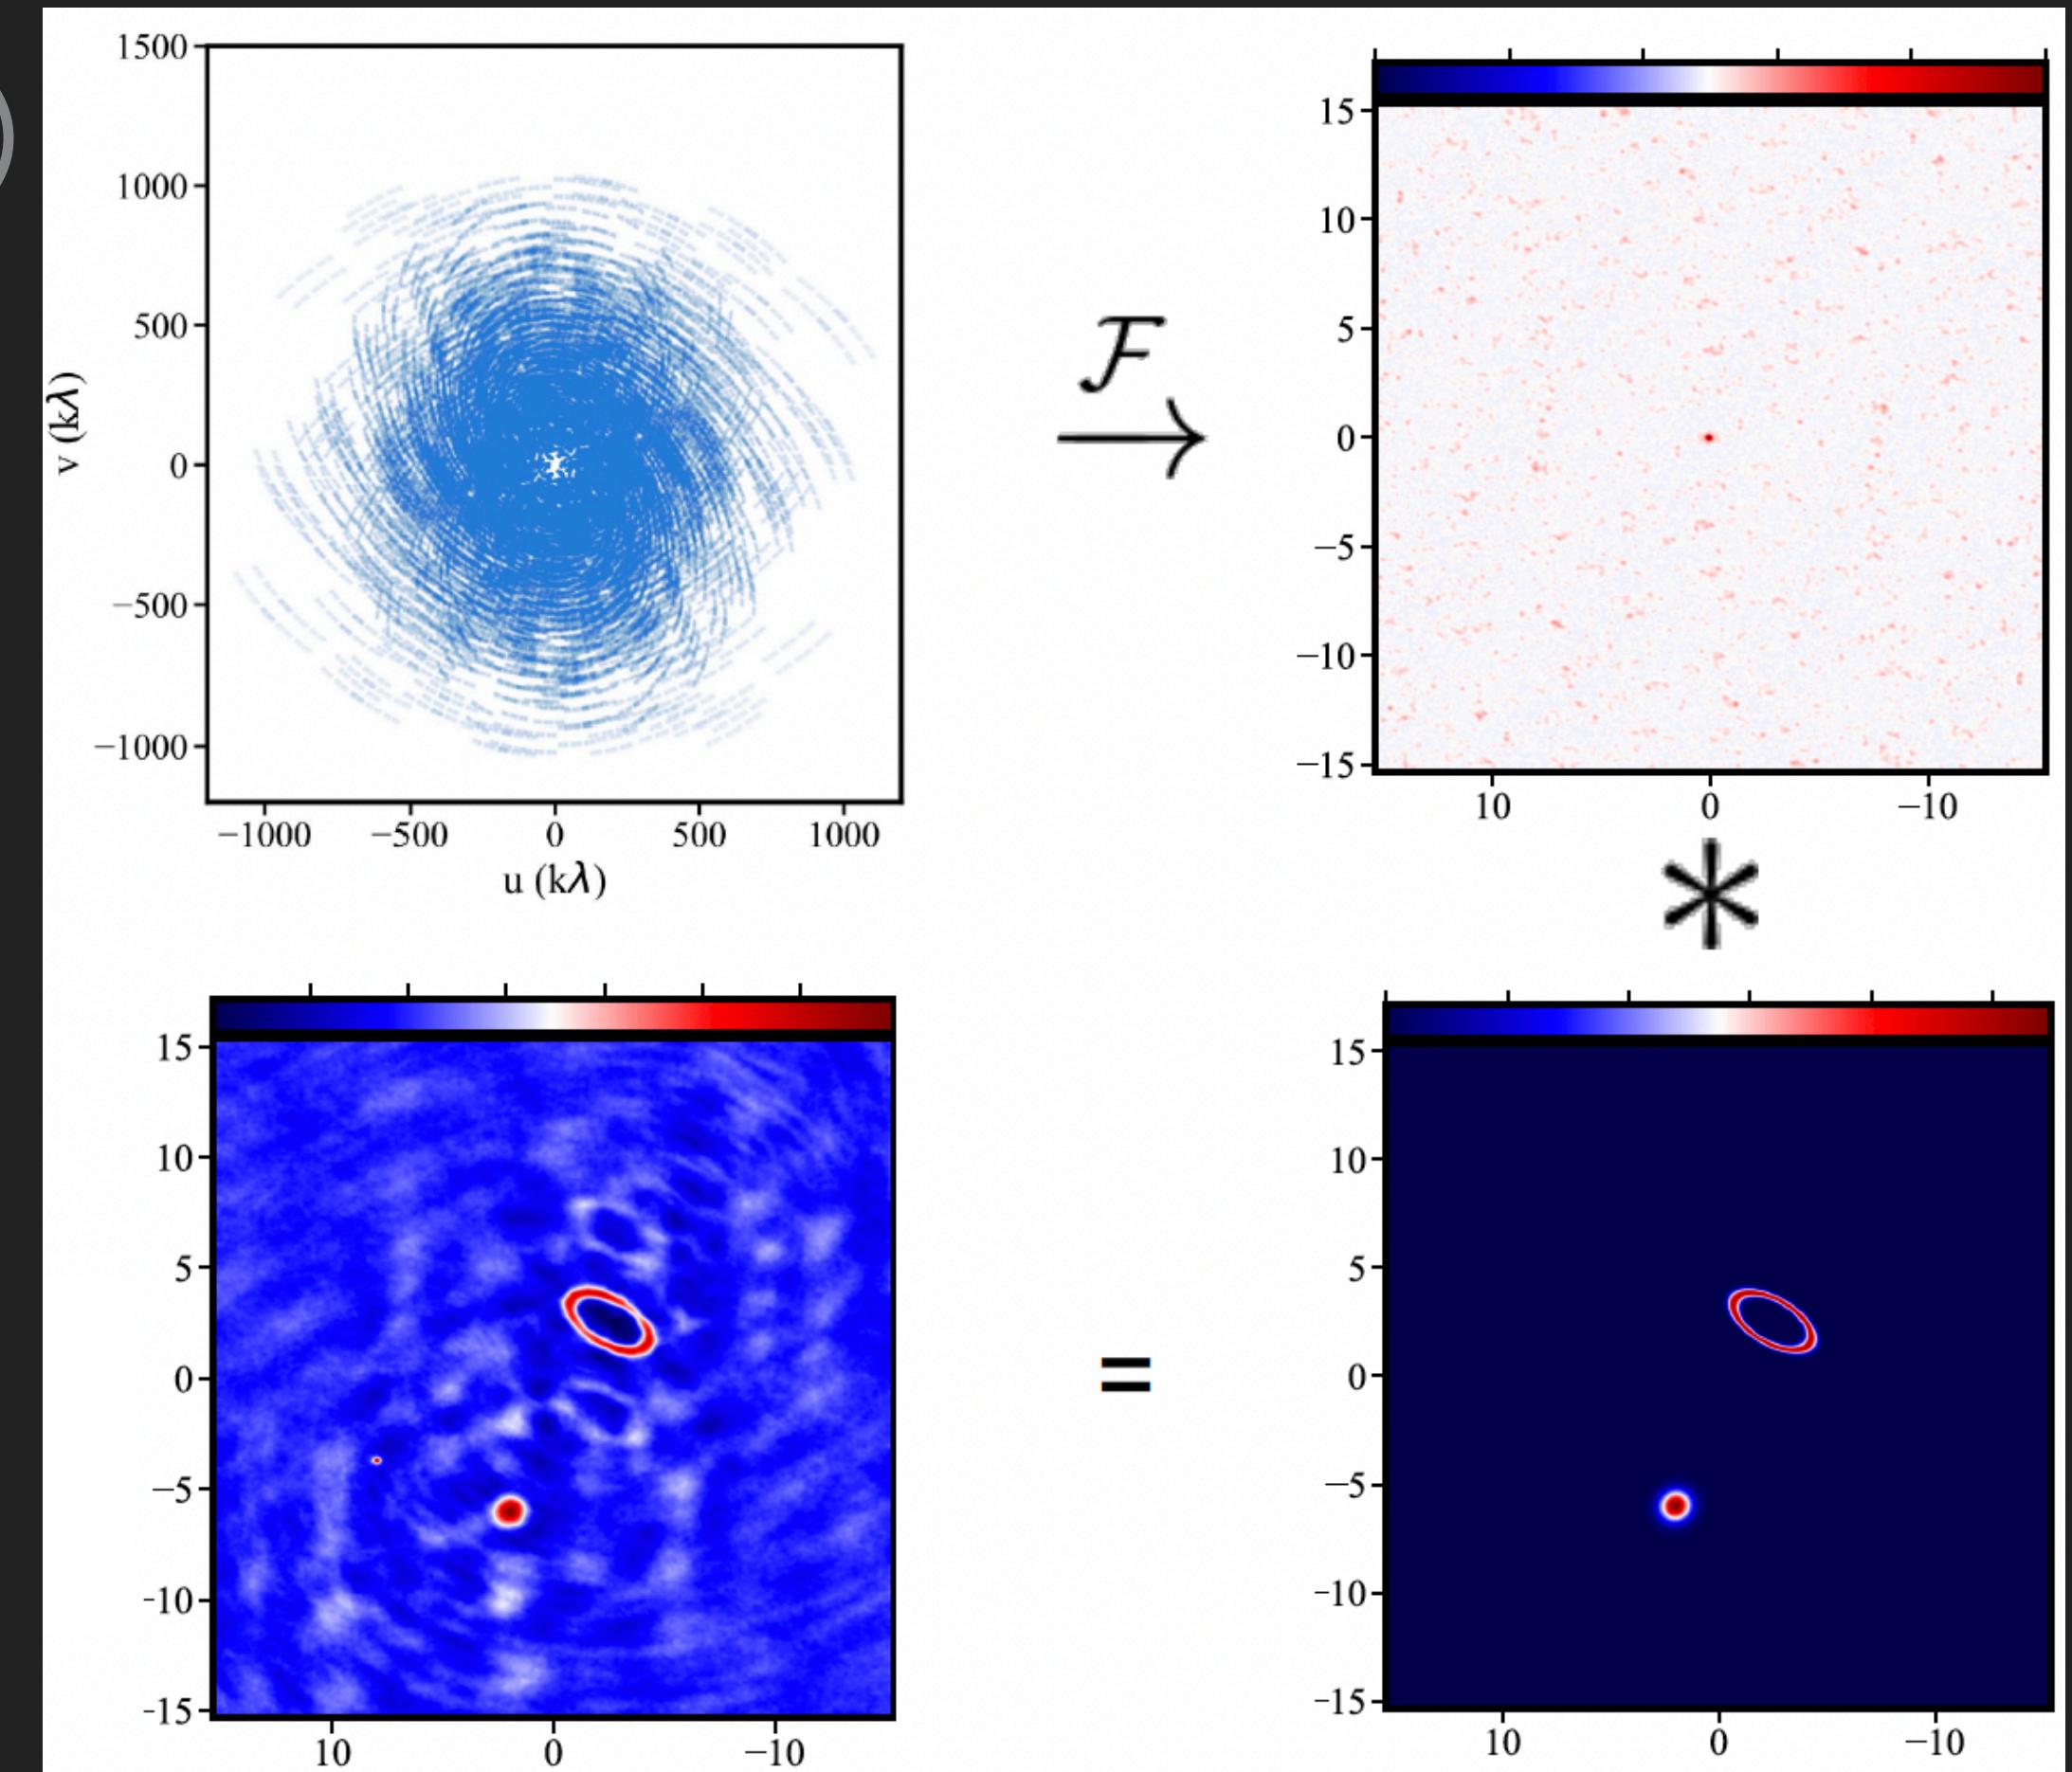

- ▶ Radio waves are too long to create high-resolution images with one telescope
- ▶ Signals from multiple dishes are combined to create sky image
- ▶ Creates effective “telescope” as large as the distance between antennas
- ▶ Rather than measuring the sky brightness itself, measures its Fourier transform

NRAO/AUI/NSF

## RADIO DATA CHALLENGES

- ▶ Radio datasets are massive (up to 100s GB)
- ▶ Creating an image requires a lot of computing power
  - ▶ FT, convolutions, and more
- ▶ Limited opportunity for parallelization (more cores = good, but everything must be on one node), and memory intensive
- ▶ Can still use HTC (super-powered laptop)

## MOVING TO CHTC

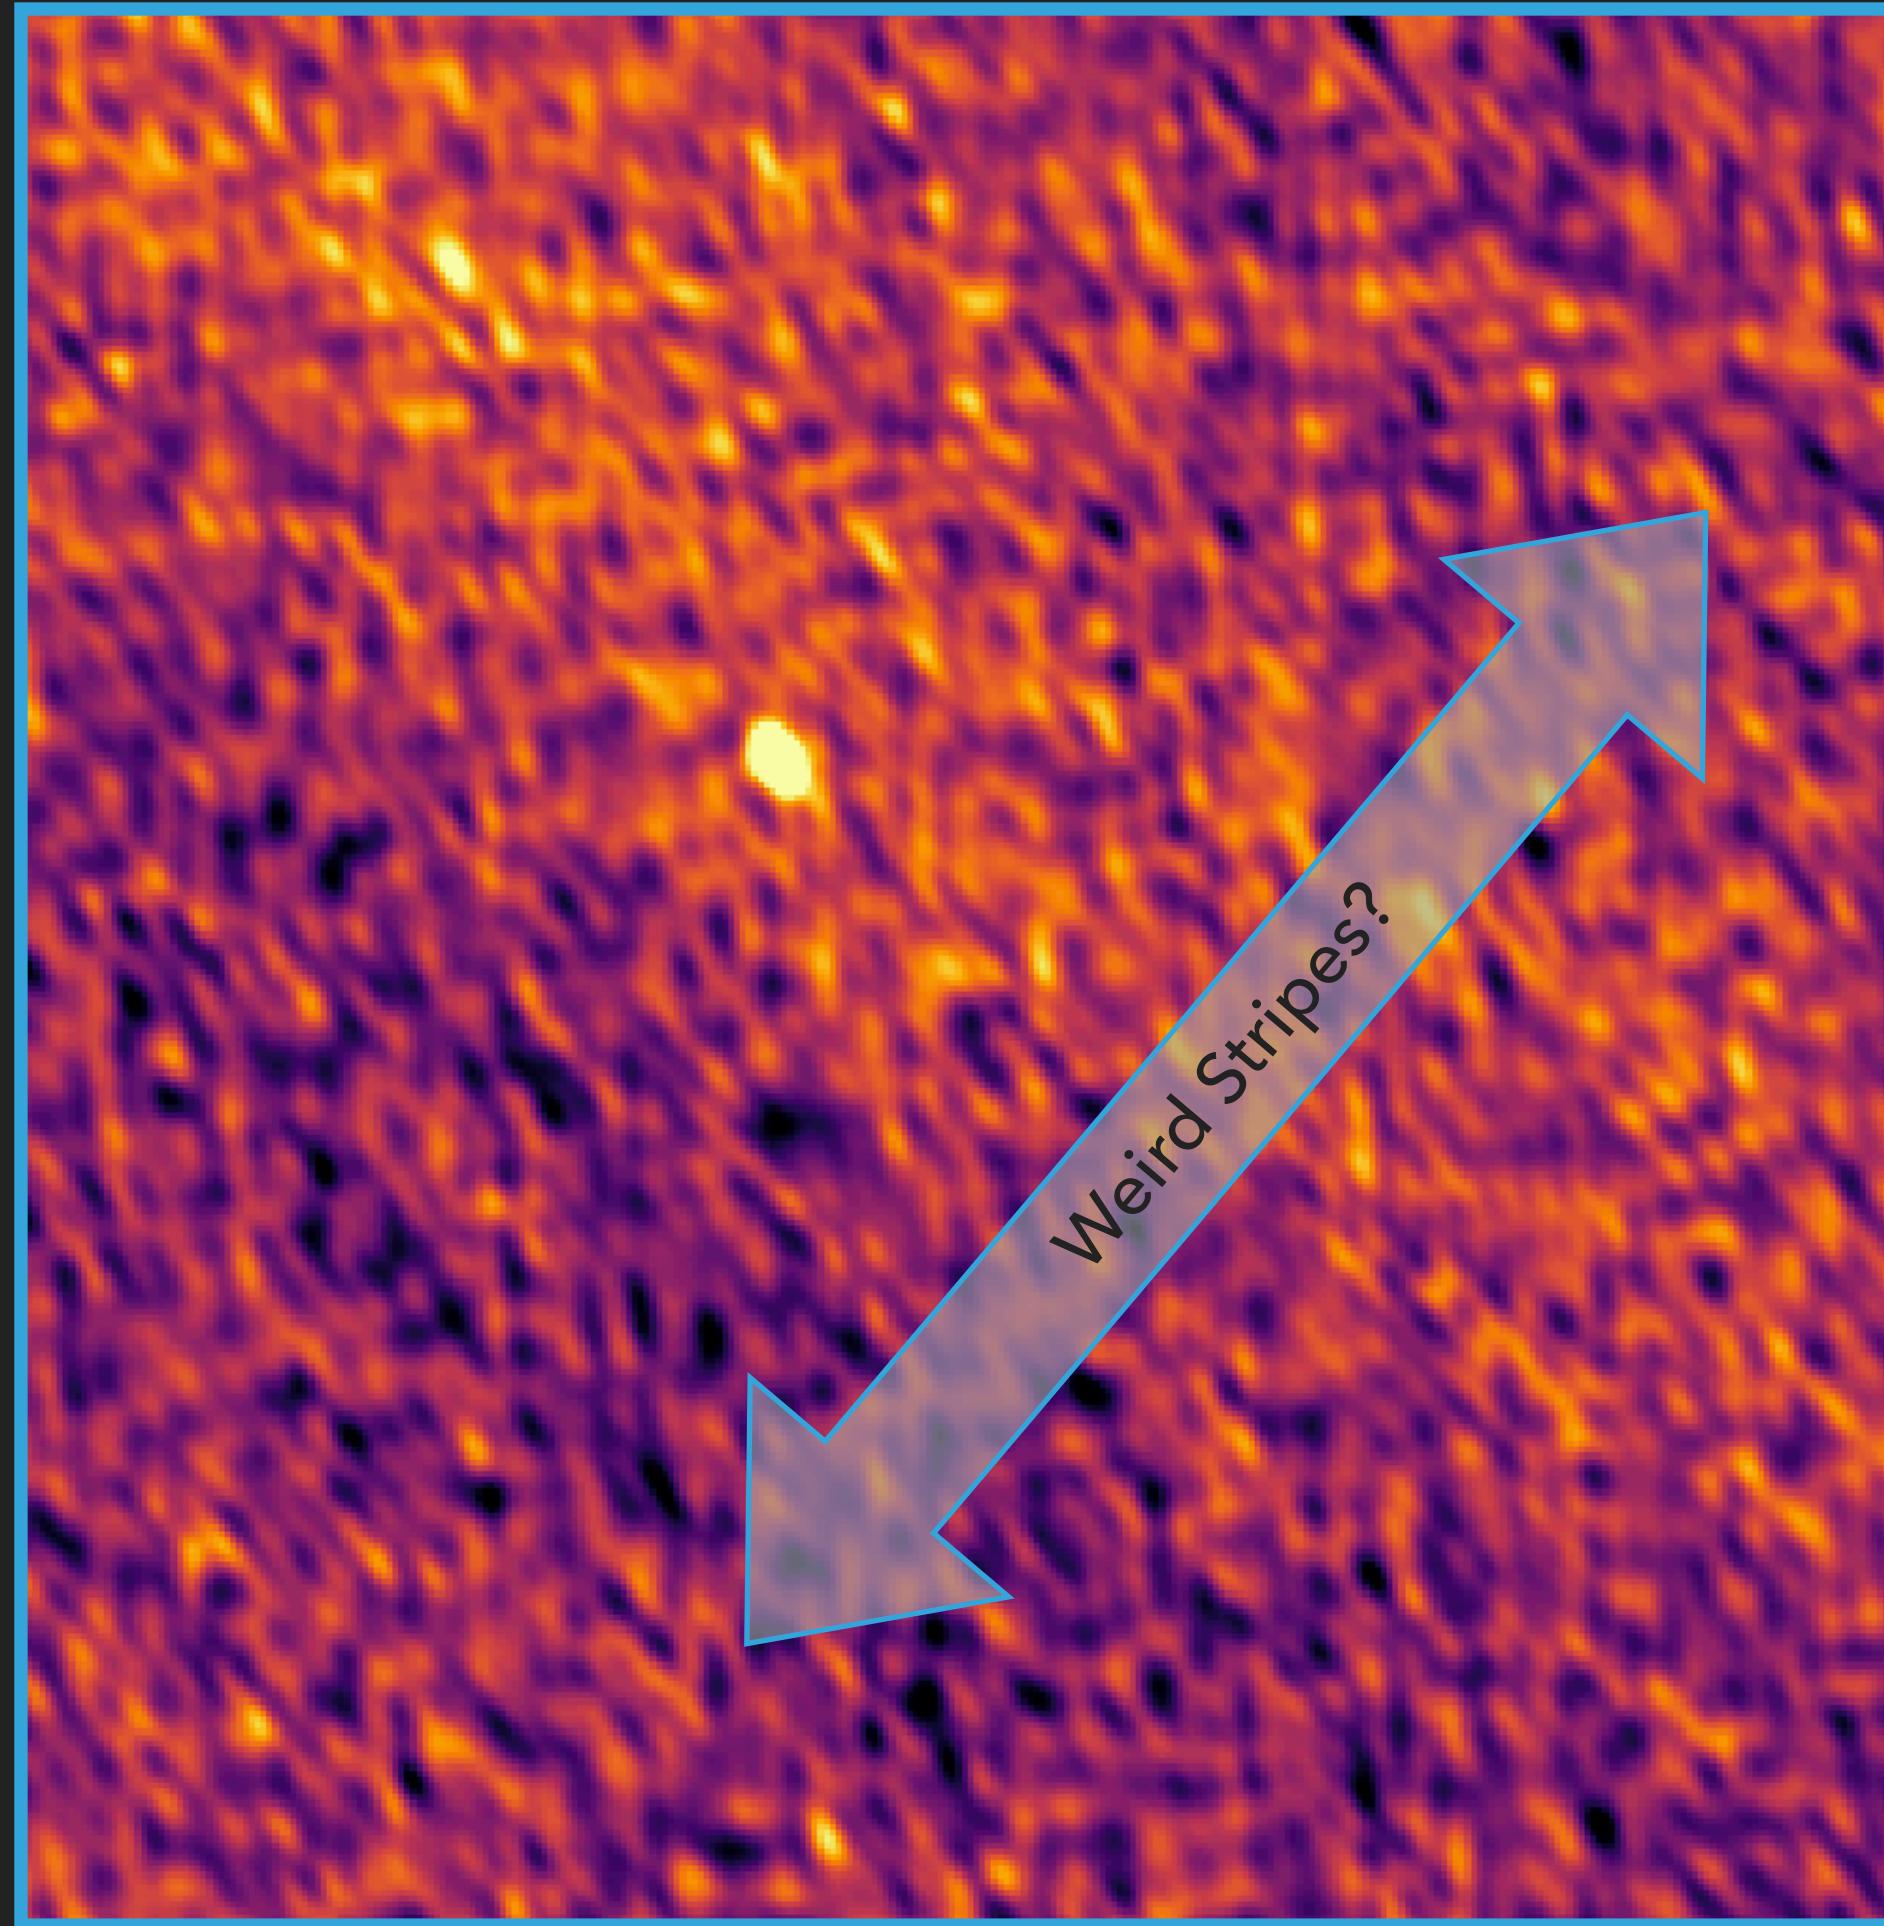

- ▶ >1 month to get everything set up
- ▶ Custom software in a container, MPI
- ▶ Normally interactive process moved to scripts
- ▶ Huge datafiles required special transfer procedures
- ▶ UW CHTC staff have been extremely helpful!

```
Bootstrap: docker
From: ubuntu:24.04
```

```
%post
```

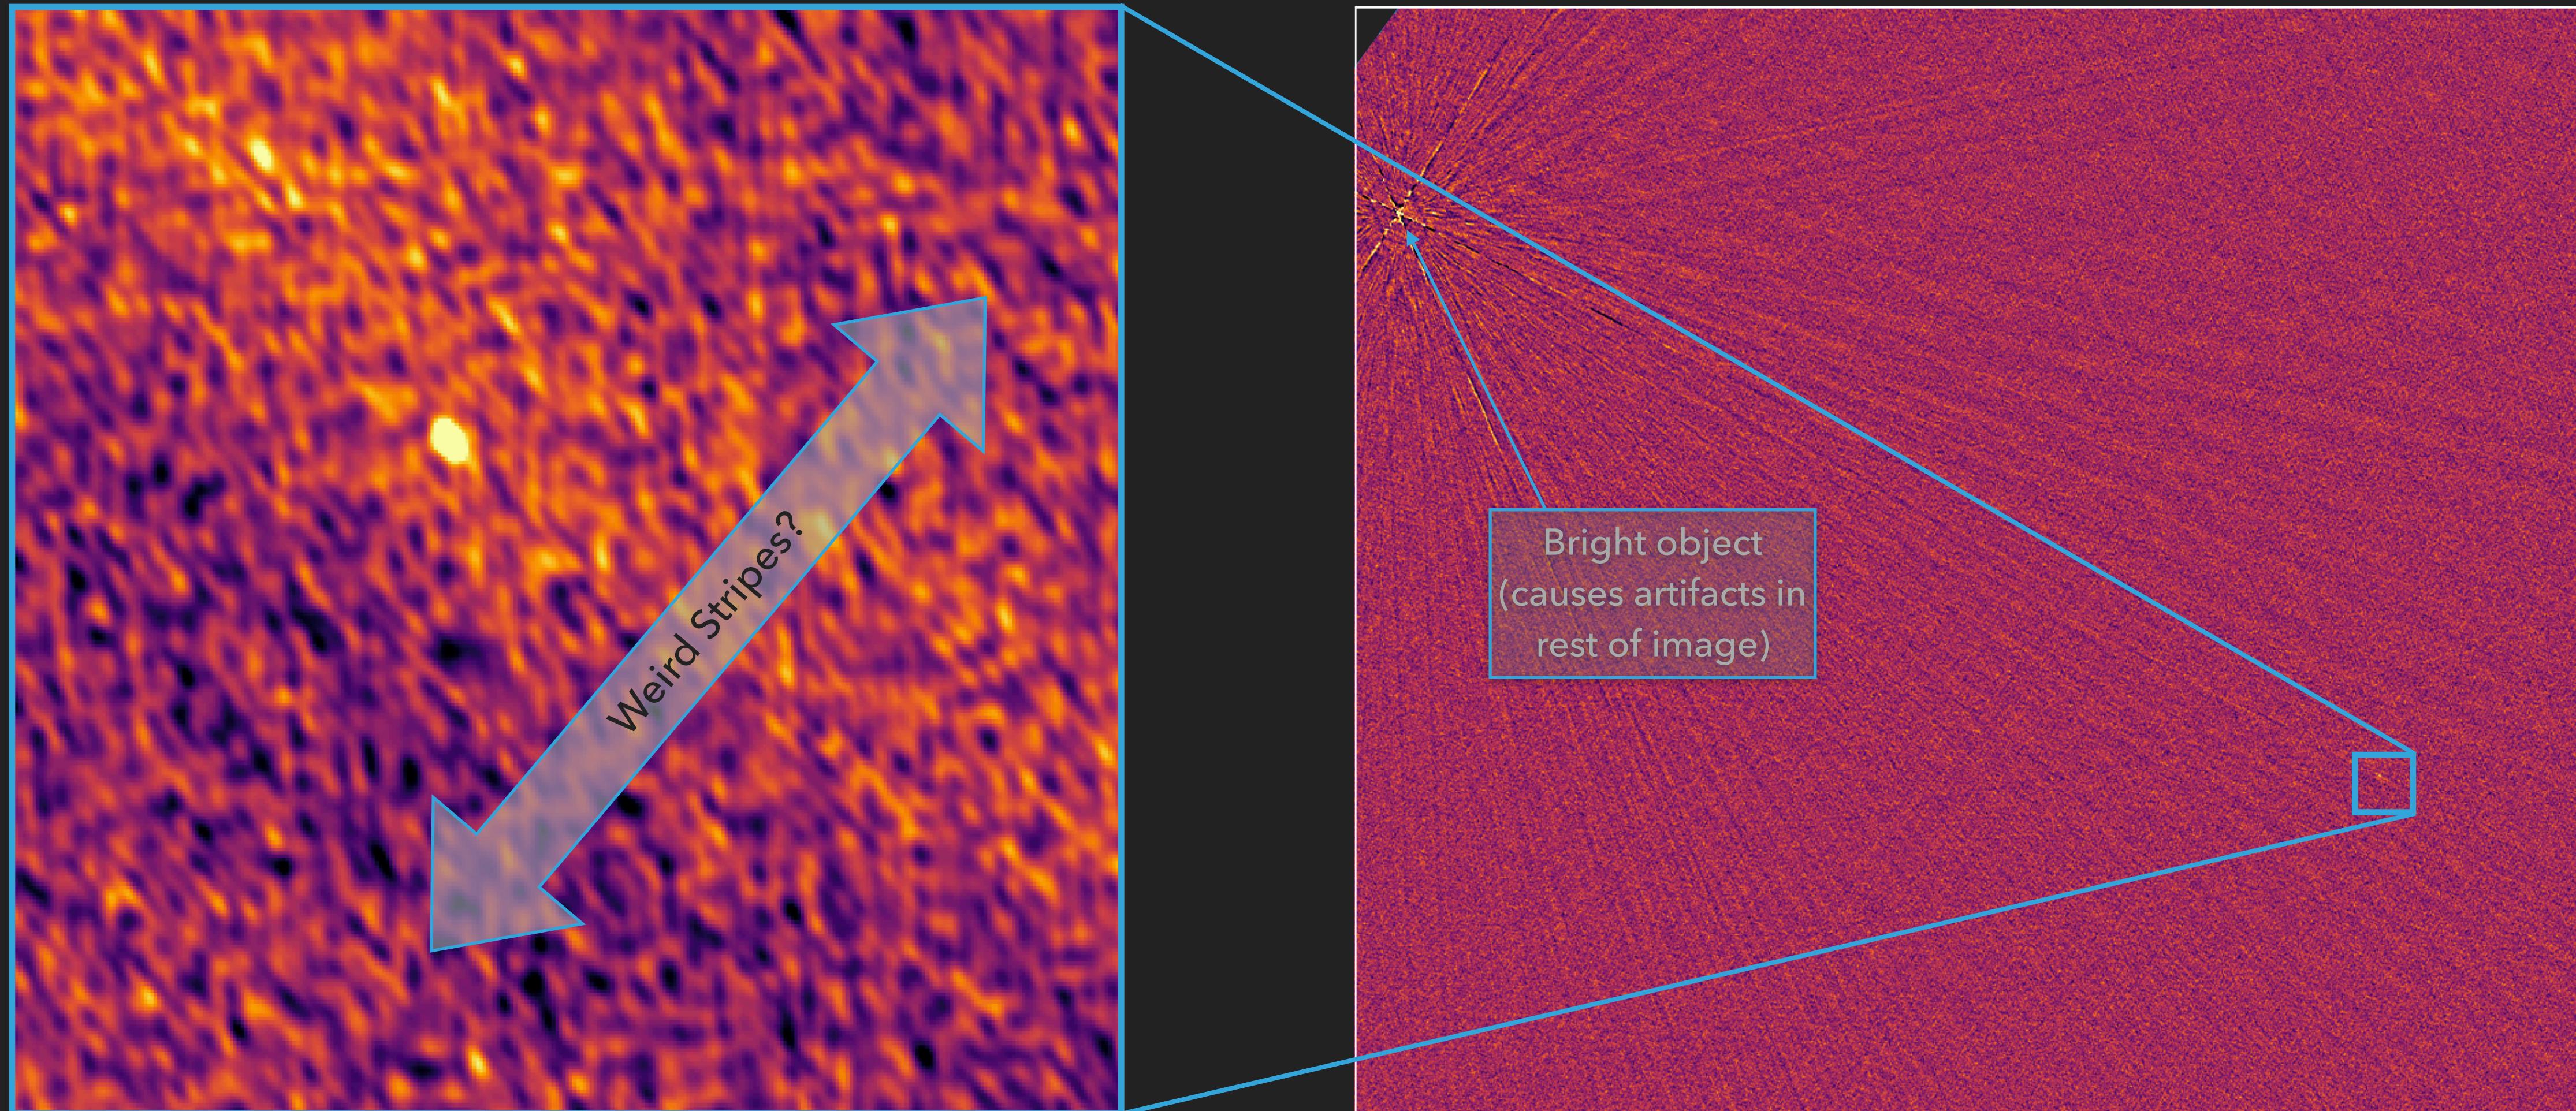

```
apt-get update -y --allow-insecure-repositories
apt-get install python3.12-venv -y
alias python=python3.12
python -m venv env --upgrade-deps
. env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==1.26.4
pip install matplotlib
pip install scipy
apt-get install ImageMagick*
apt-get install gfortran -y
apt-get -y install libnsl2 -y
apt-get install libgslcblas0 -y
apt-get install libcanberra-gtk-module -y
apt-get install build-essential -y
apt-get install xvfb -y --allow-unauthenticated
apt-get install zstd -y --allow-unauthenticated
apt-get install parallel -y
apt-get install git -y --allow-unauthenticated
apt-get install wget -y --allow-unauthenticated
apt-get install openmpi-bin openmpi-doc
apt-get install libopenmpi-dev
apt-get install libgsl-dev -v
```

## EXAMPLE 1: A LARGE IMAGE

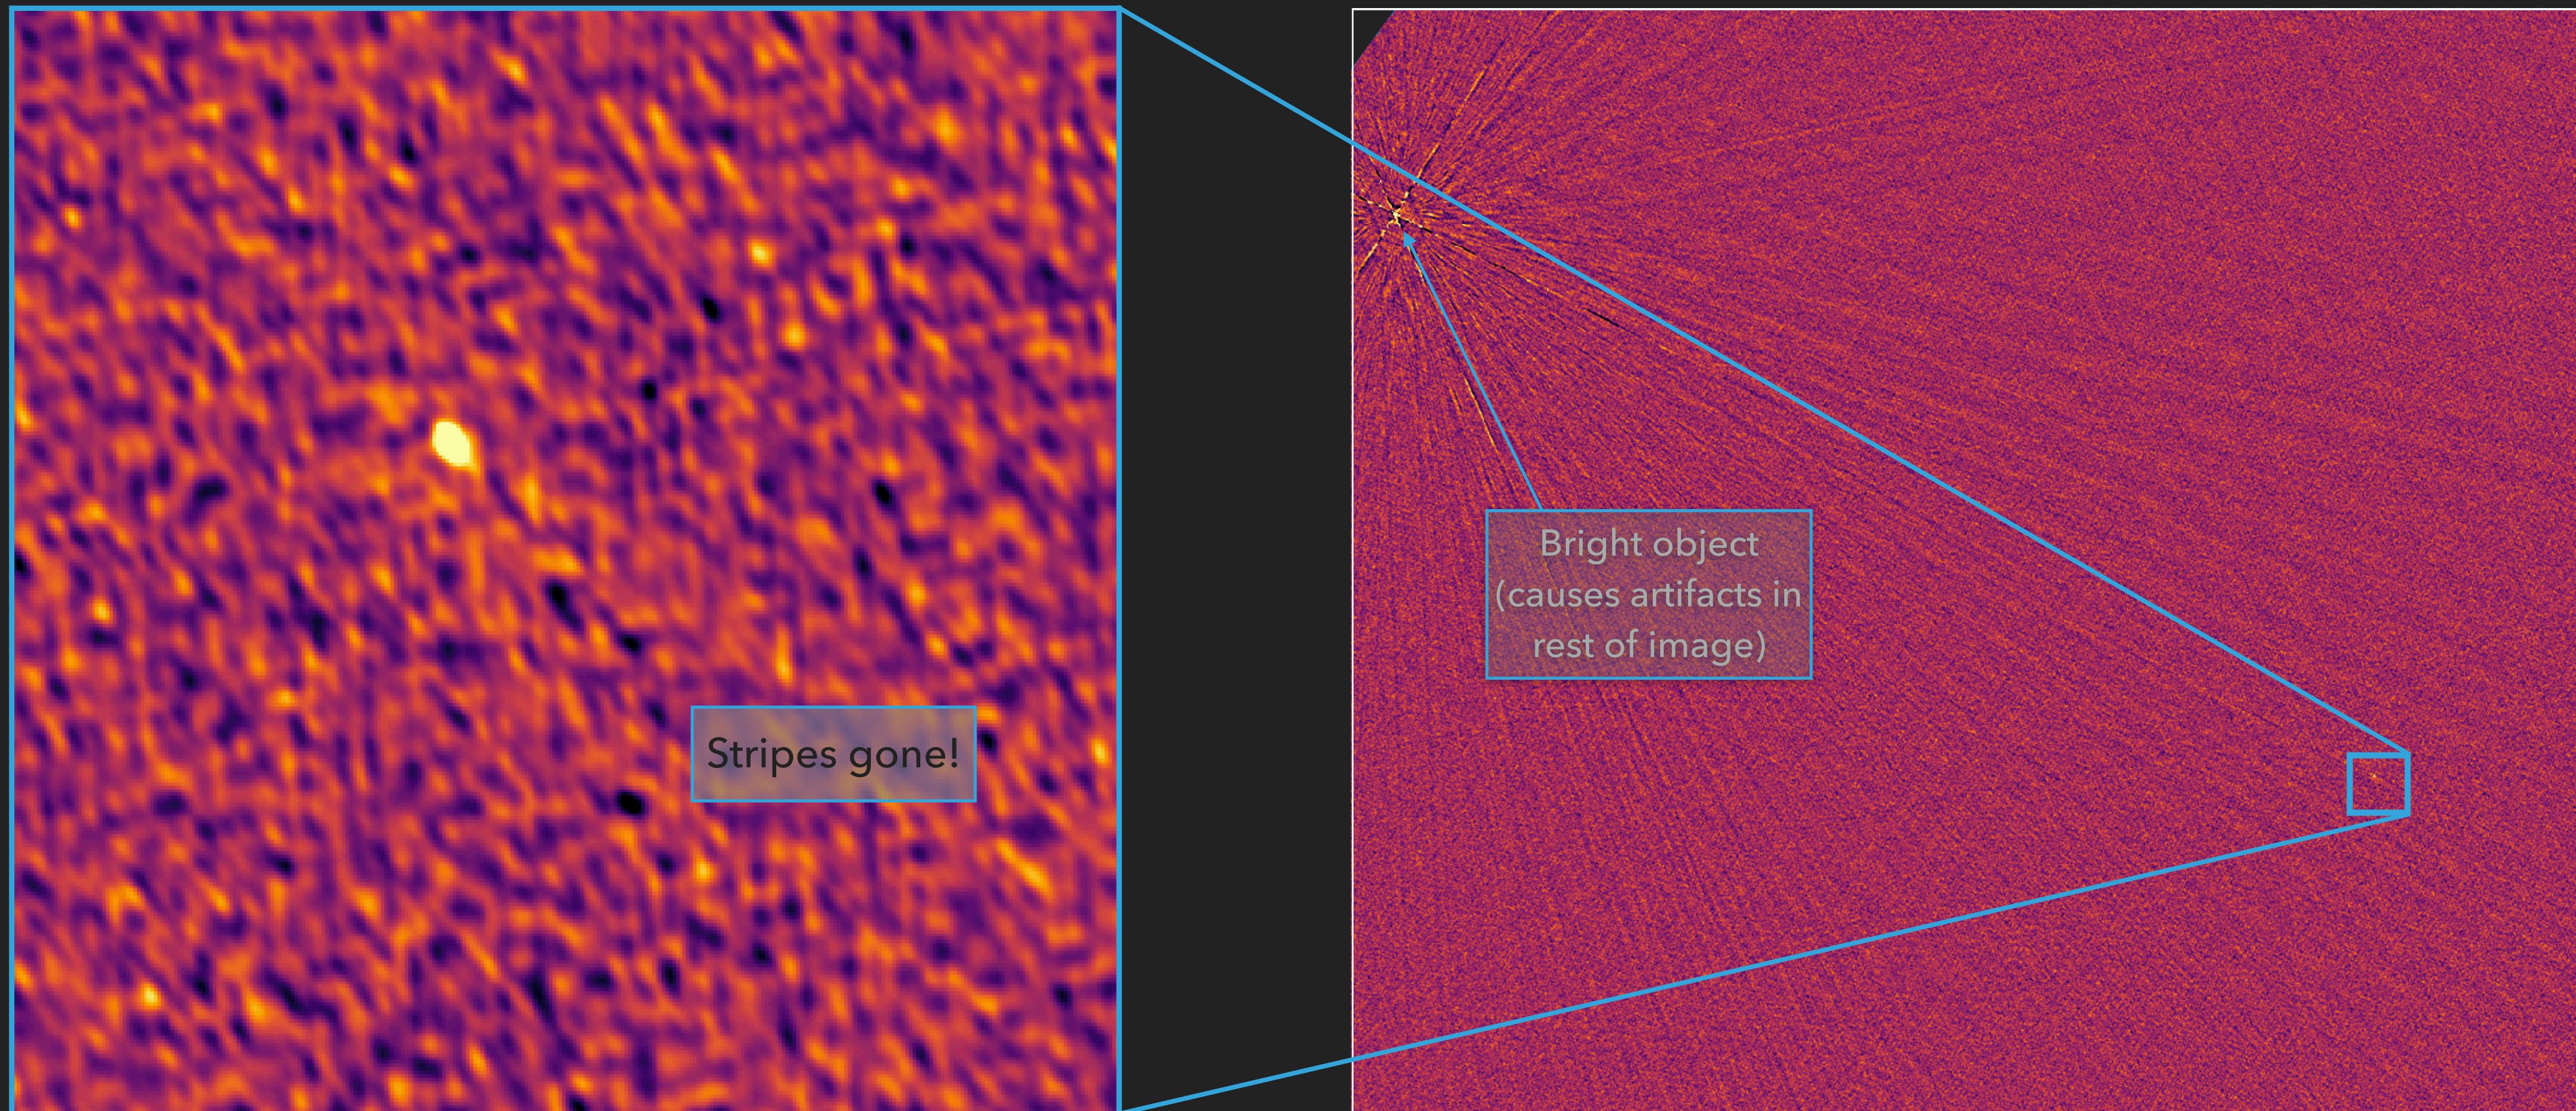

- ▶ Laptop image: 320x320 pixels
- ▶ Structured noise in image
- ▶ Probably due to bright object somewhere else in the image
  - ▶ If so, noise can be eliminated
- ▶ Created a 4320x4320 pixel image on CHTC to find out

## EXAMPLE 1: A LARGE IMAGE

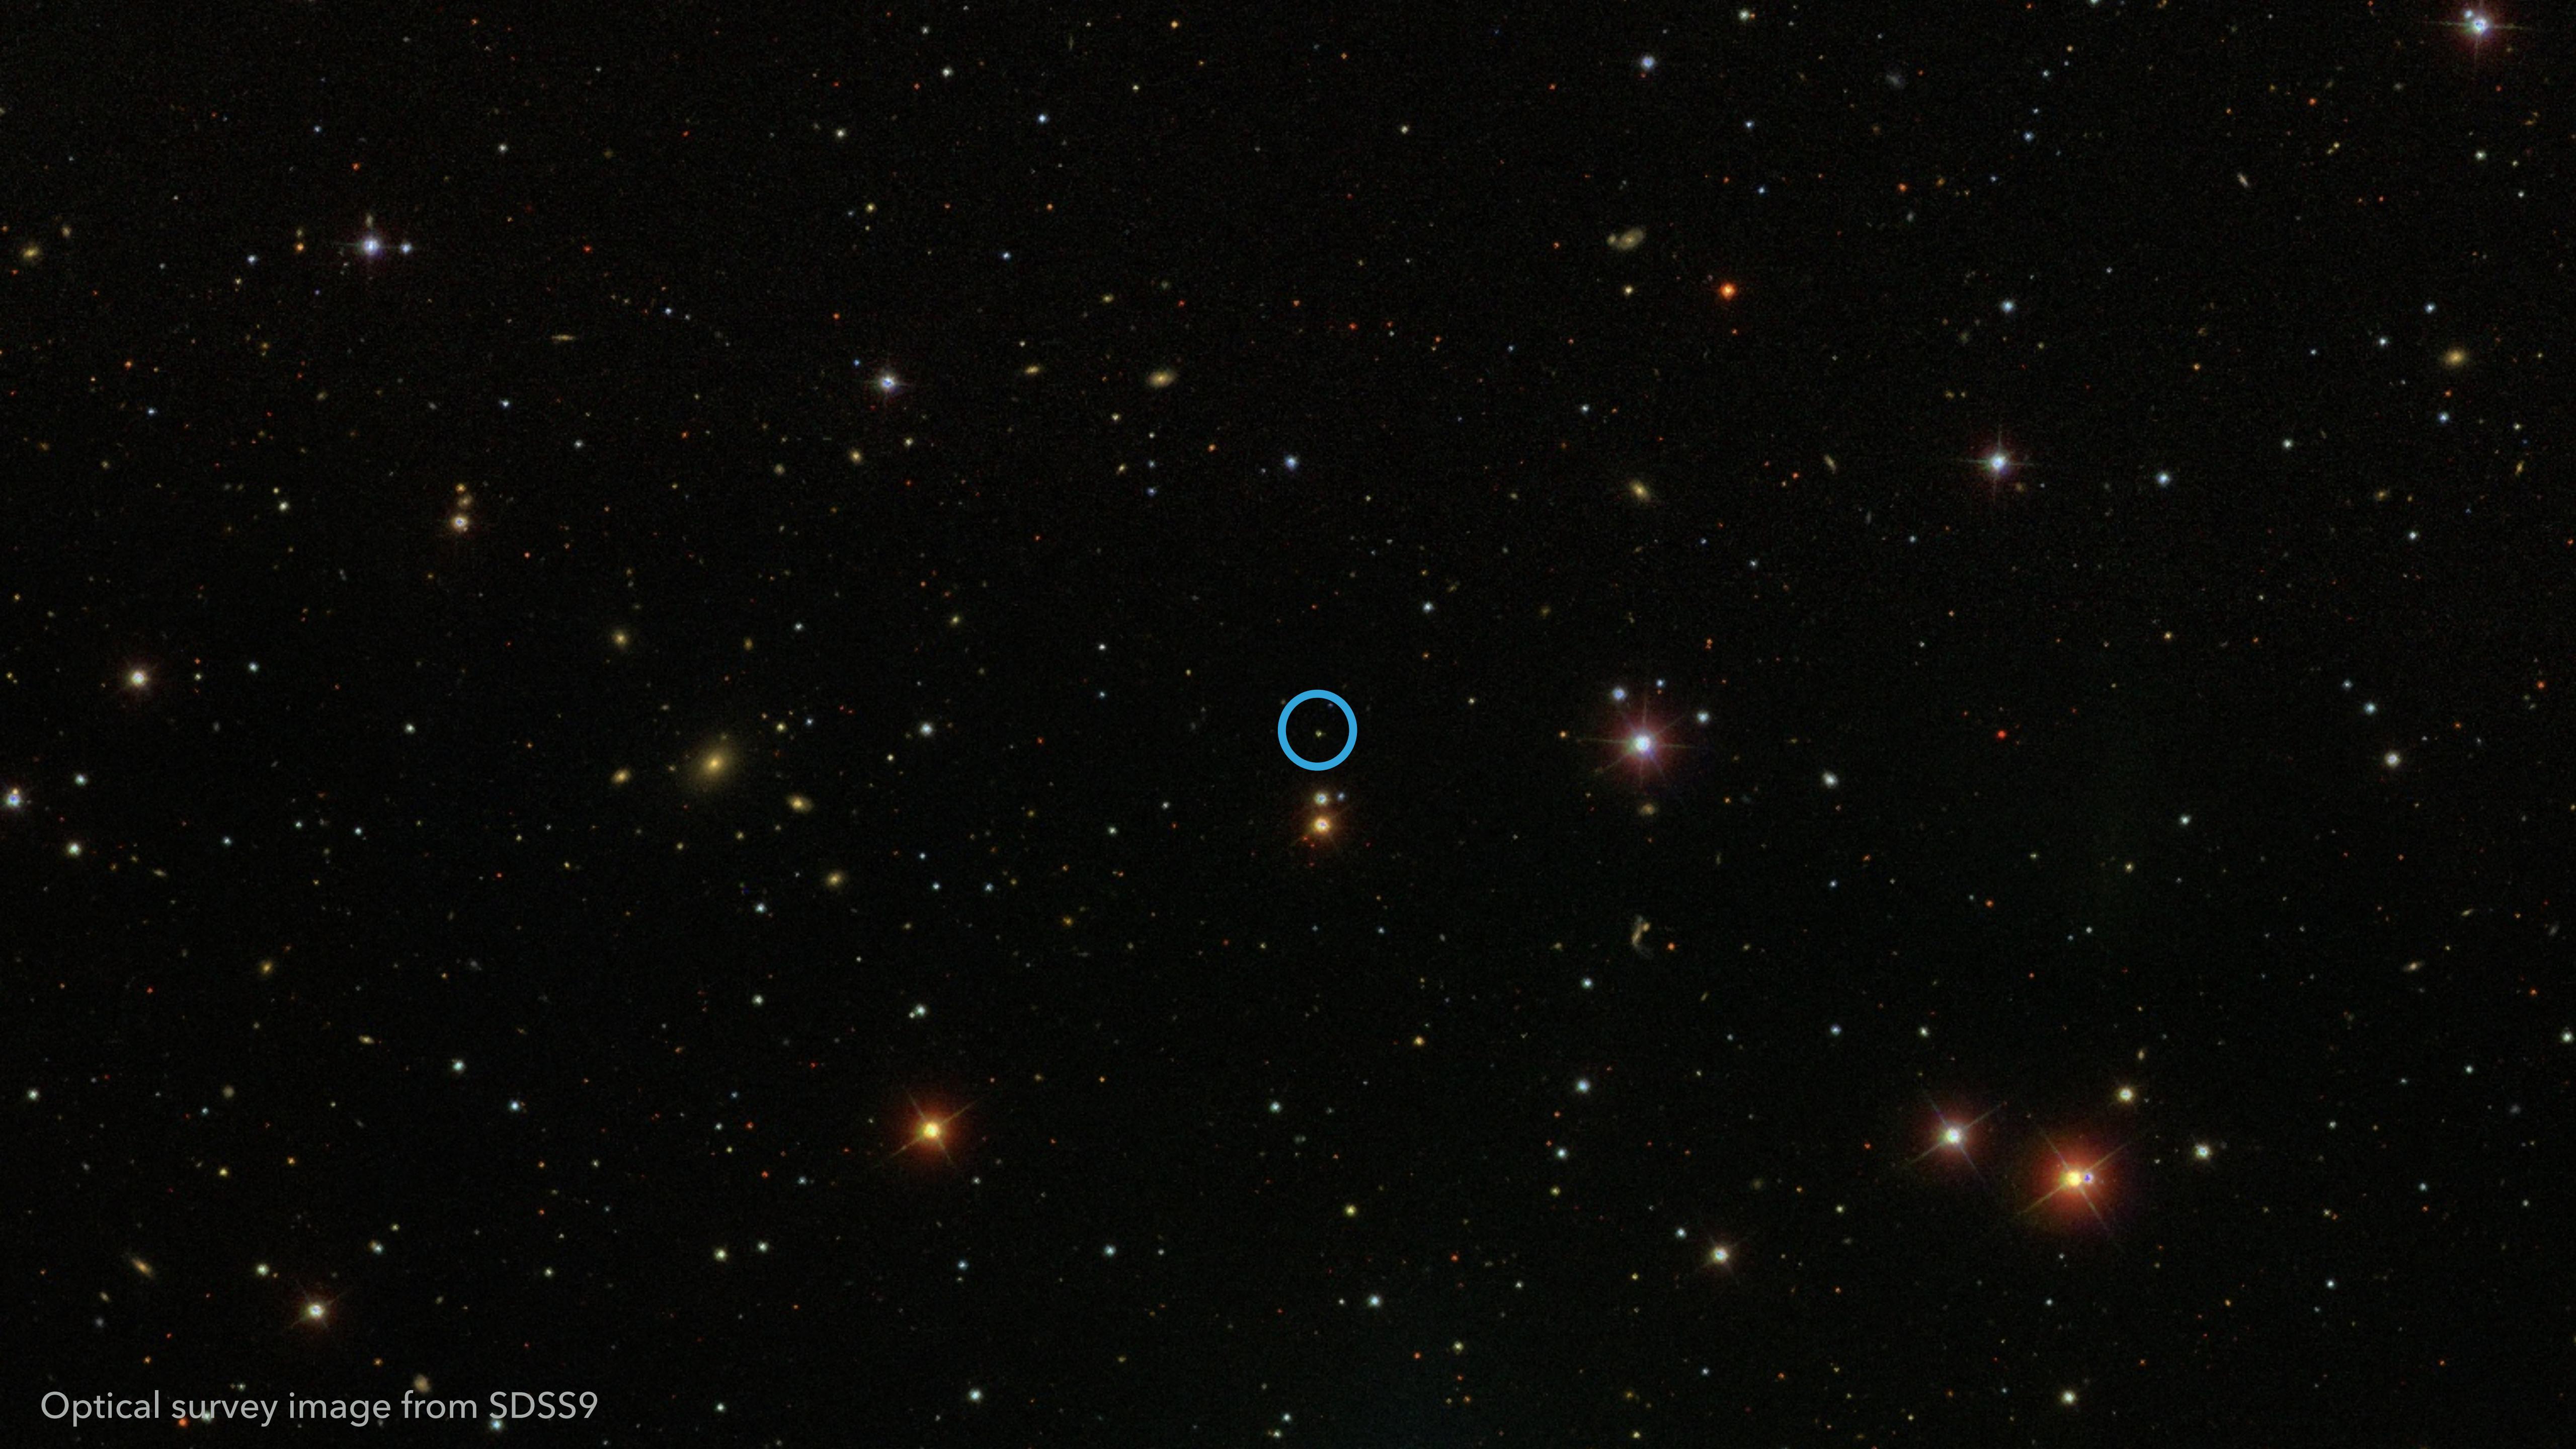

## EXAMPLE 1: A LARGE IMAGE

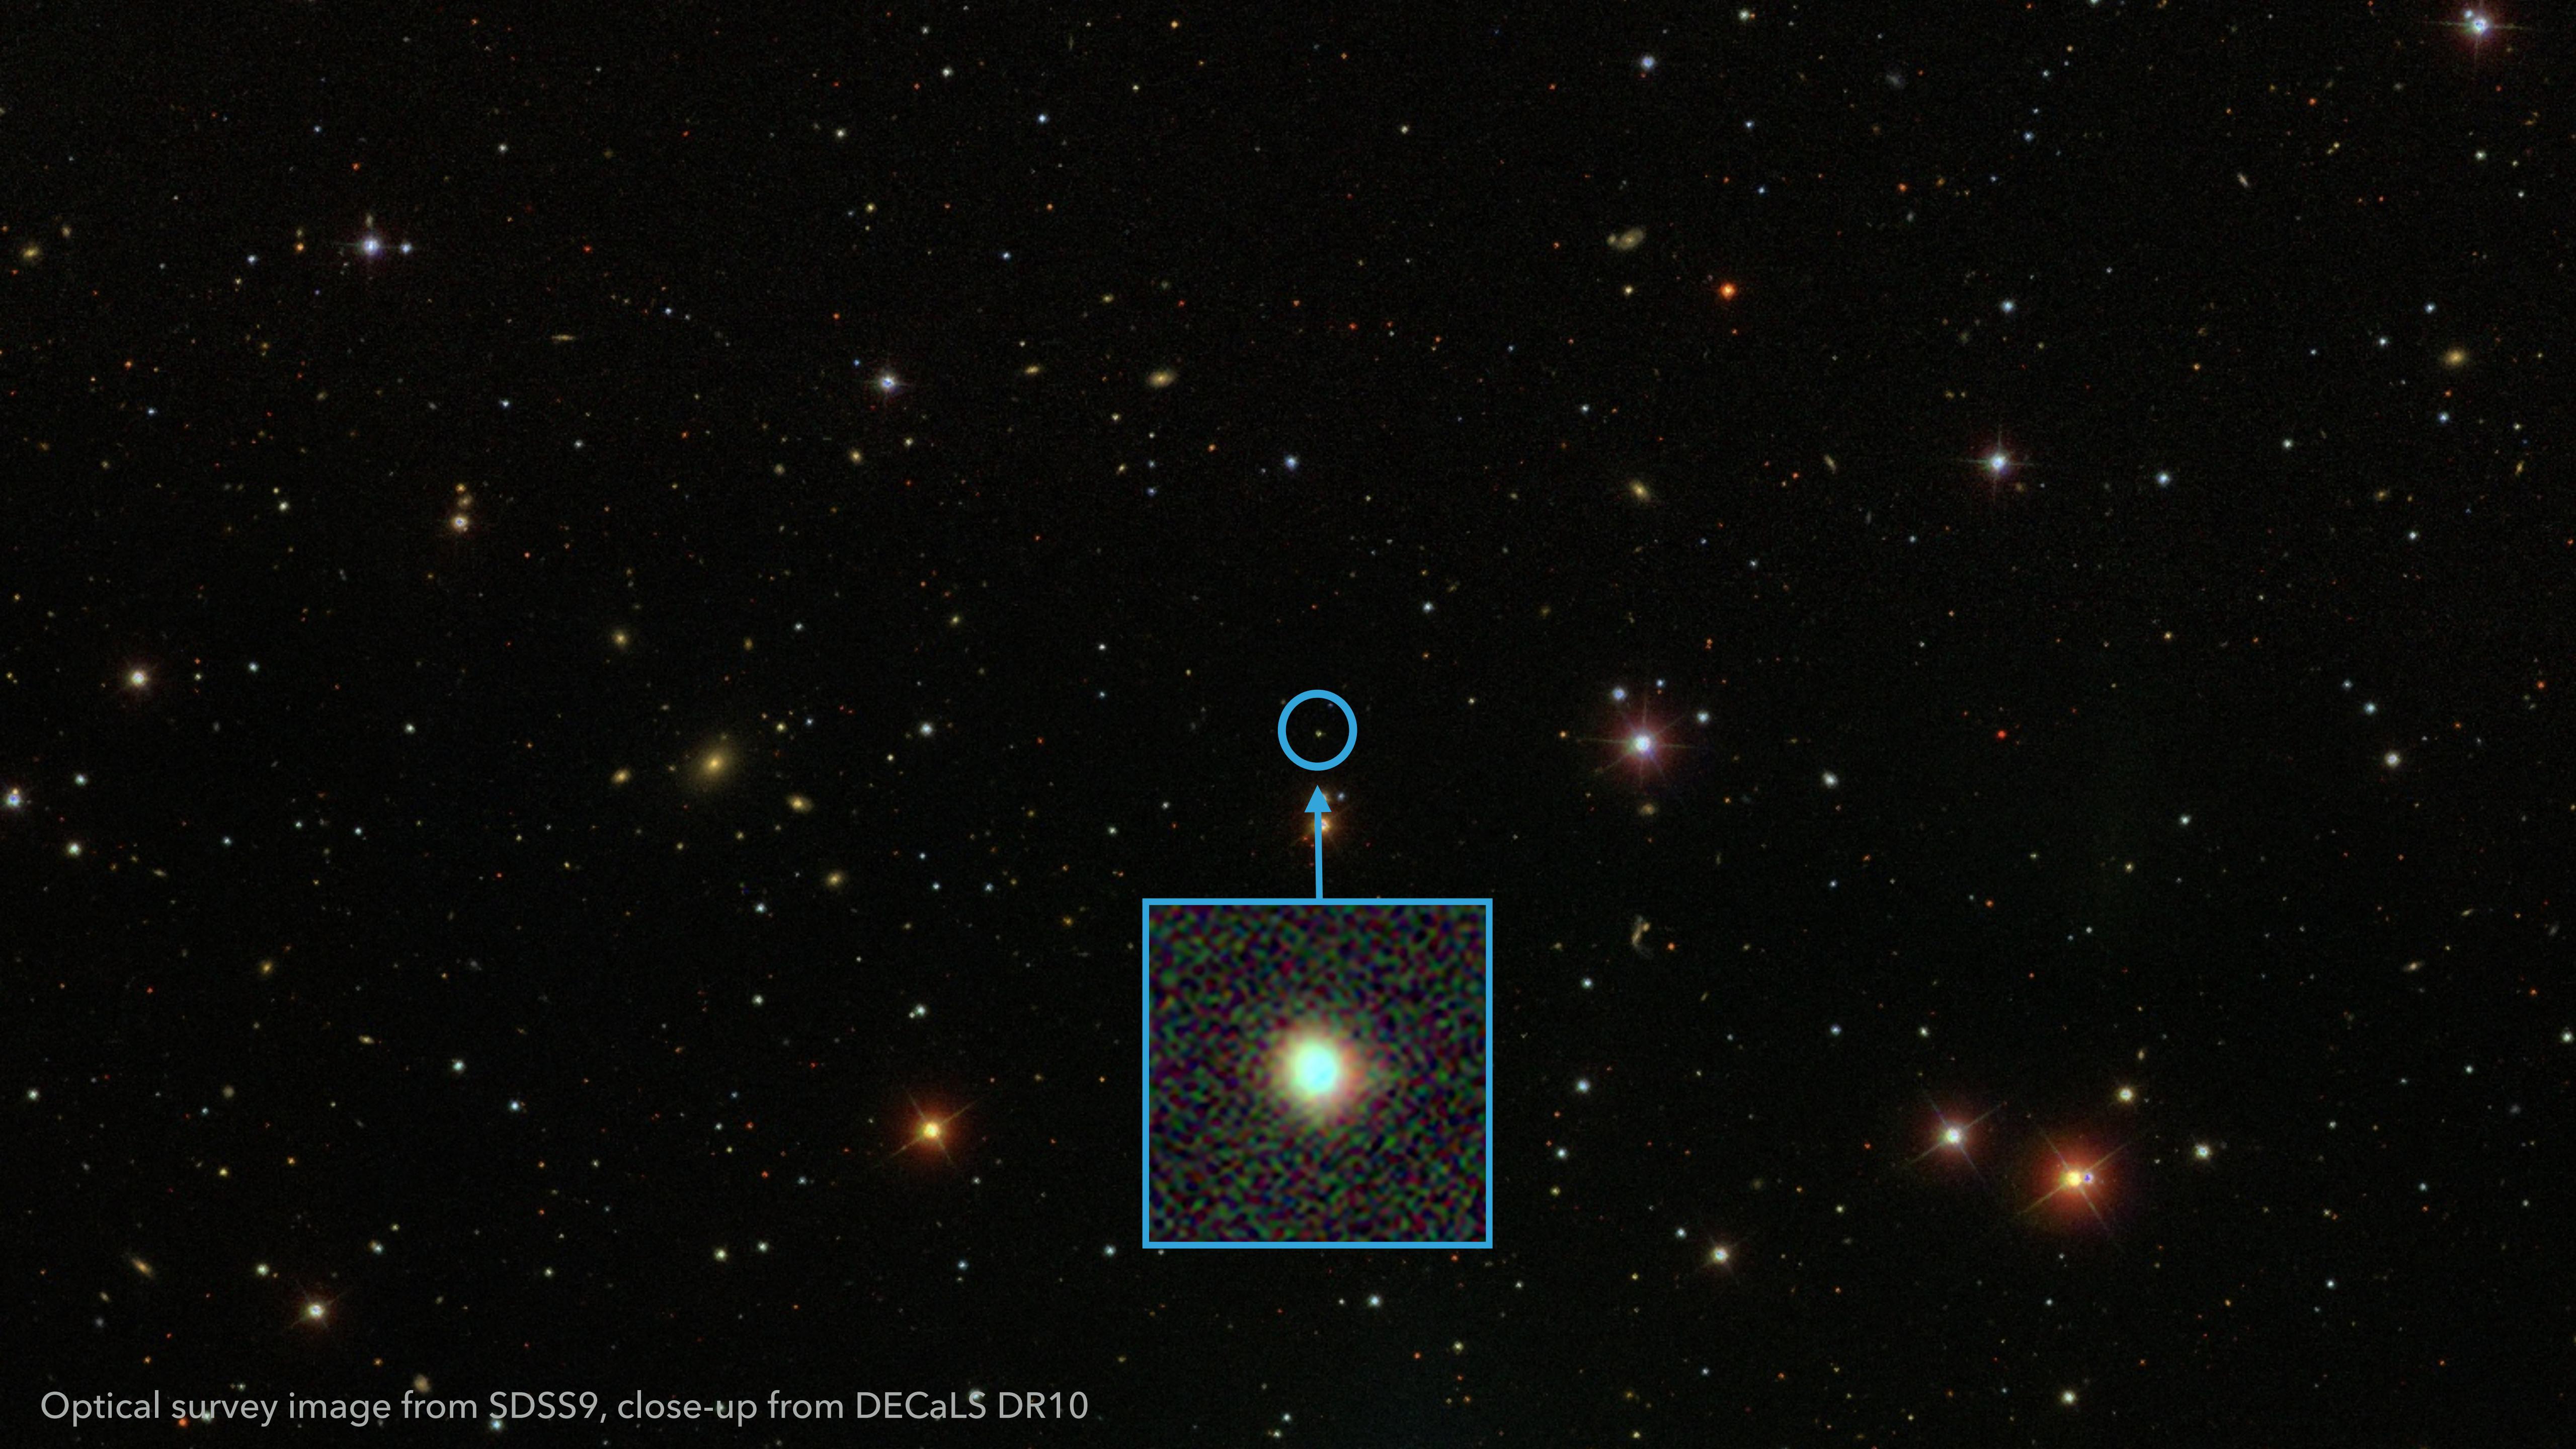

## EXAMPLE 2: MANY SOURCES IN ONE FIELD

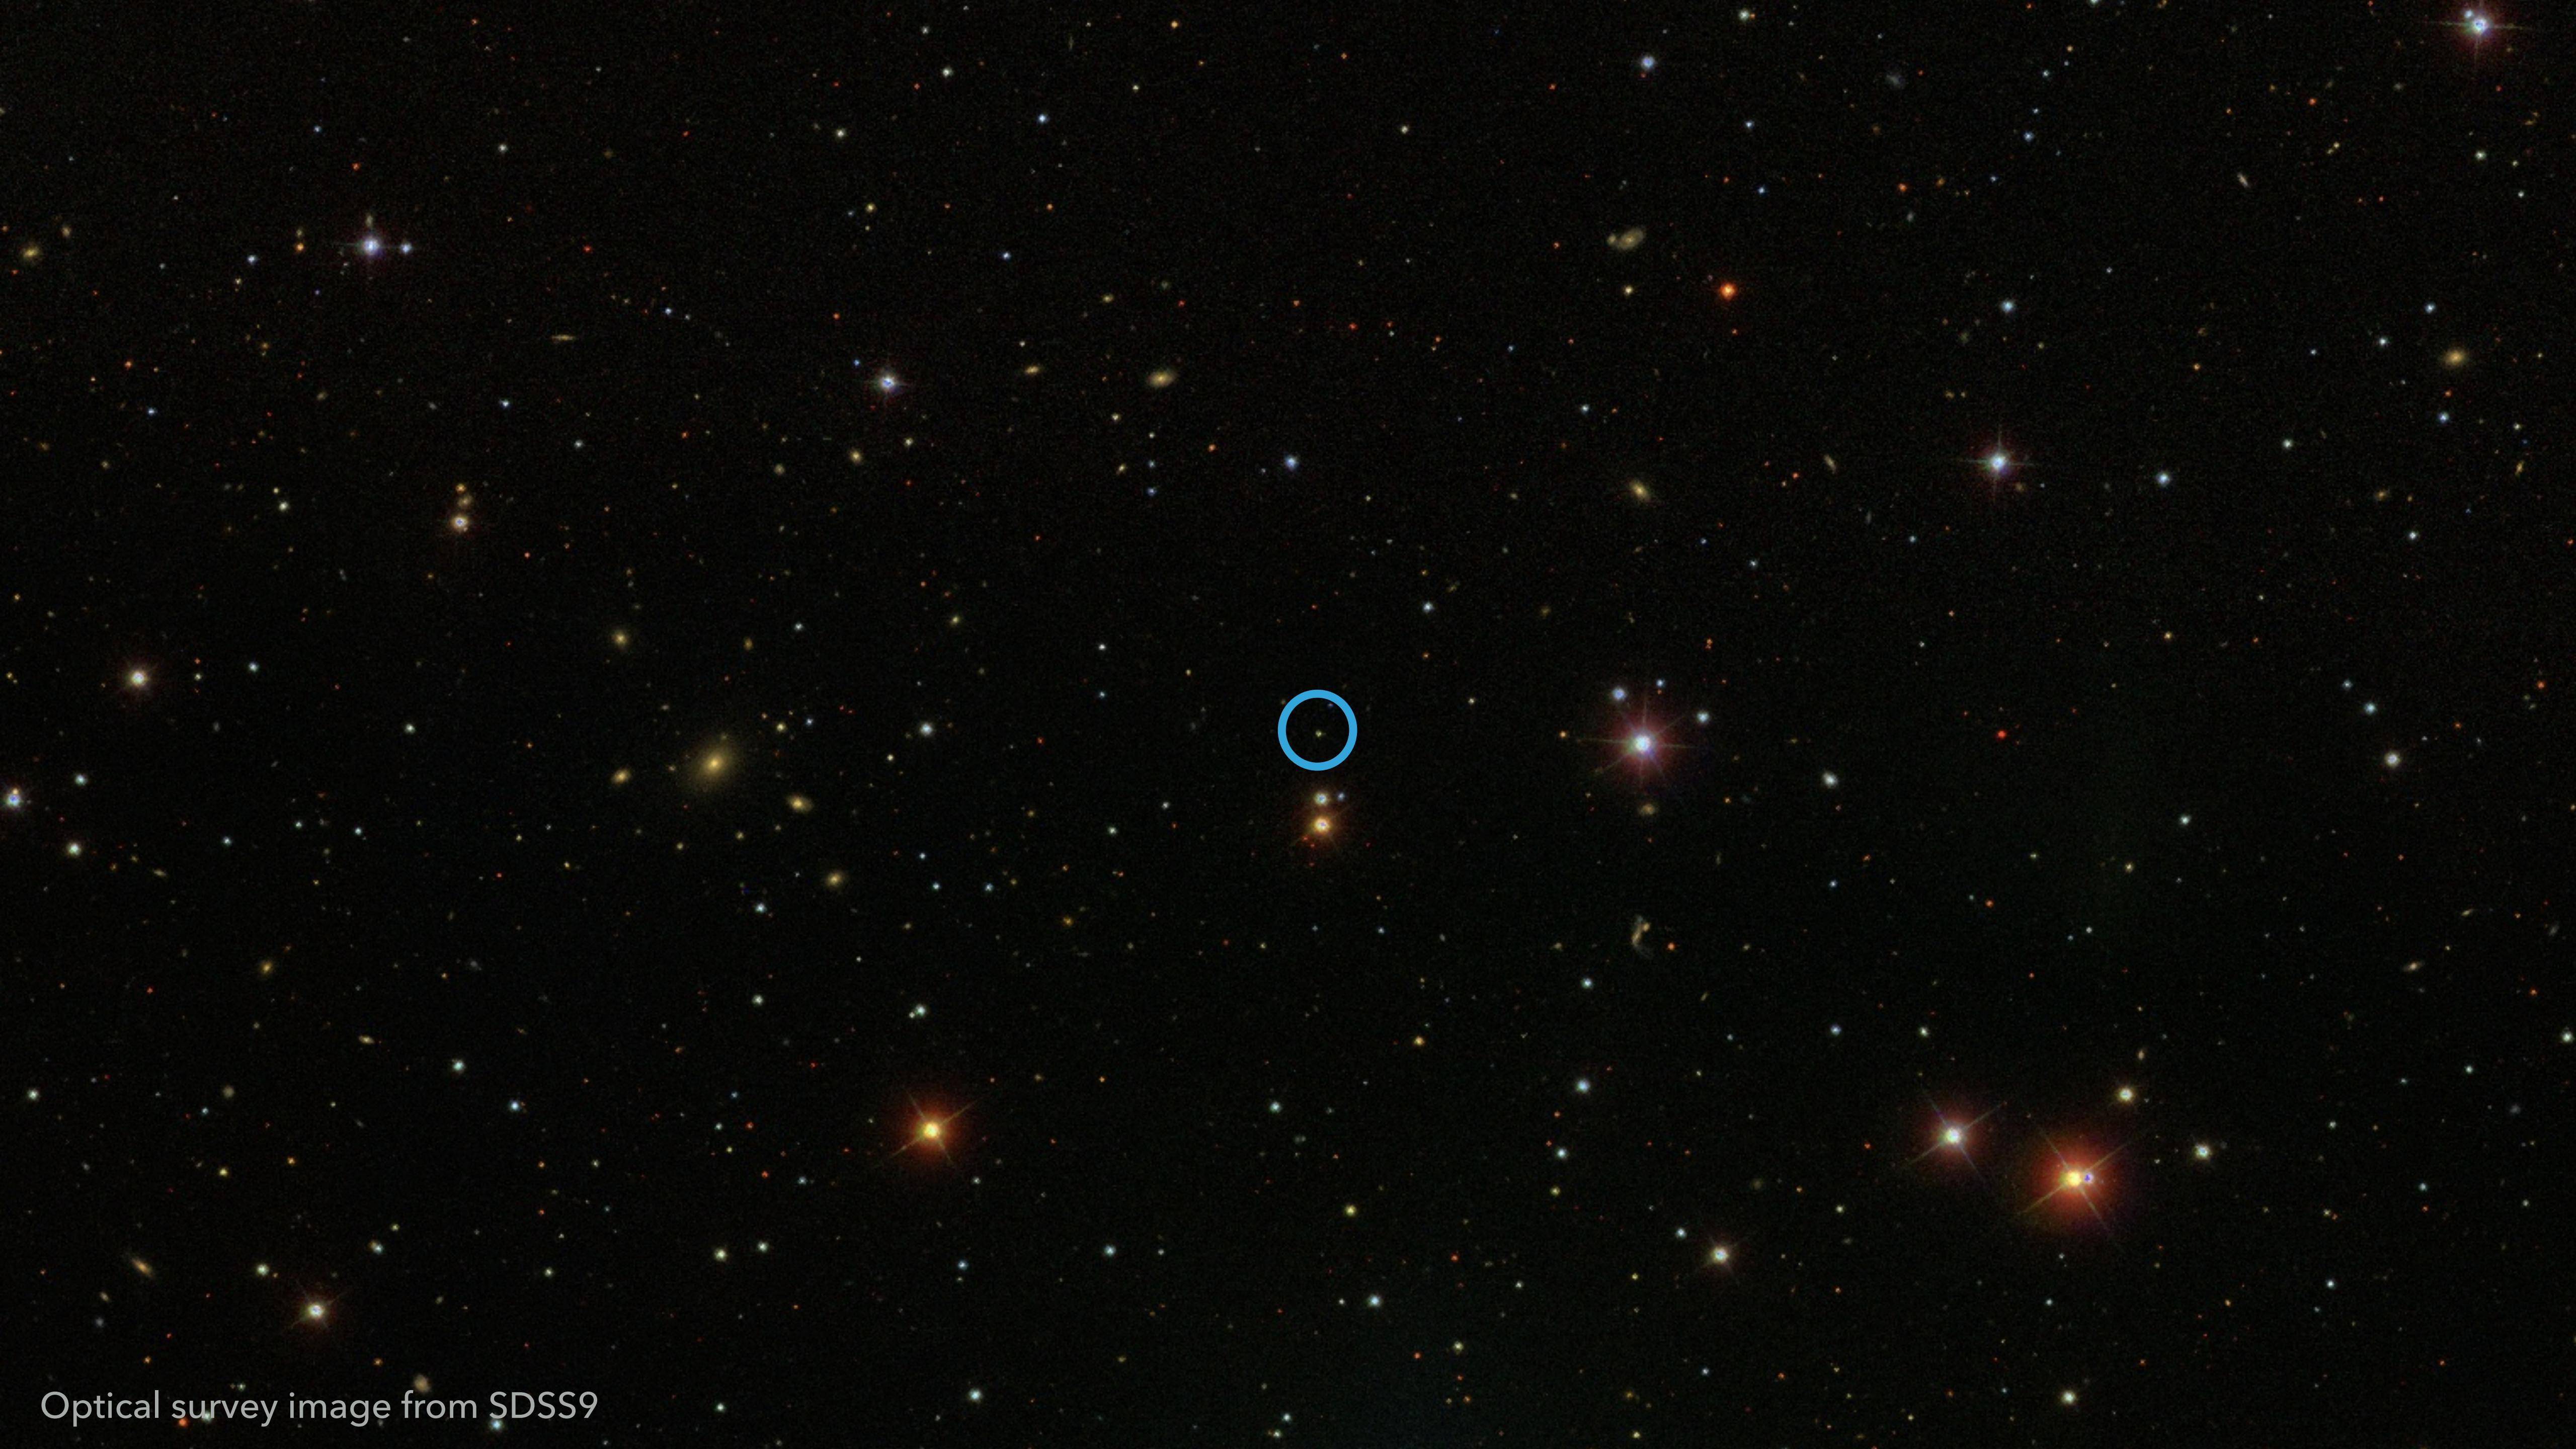

- ▶ Project: look for gravitationally lensed sources that emit radio waves
- ▶ Low-resolution survey image suggests target near many other sources
- ▶ Outlying sources can mess with image quality
- ▶ Can analyze simultaneously given enough computing power

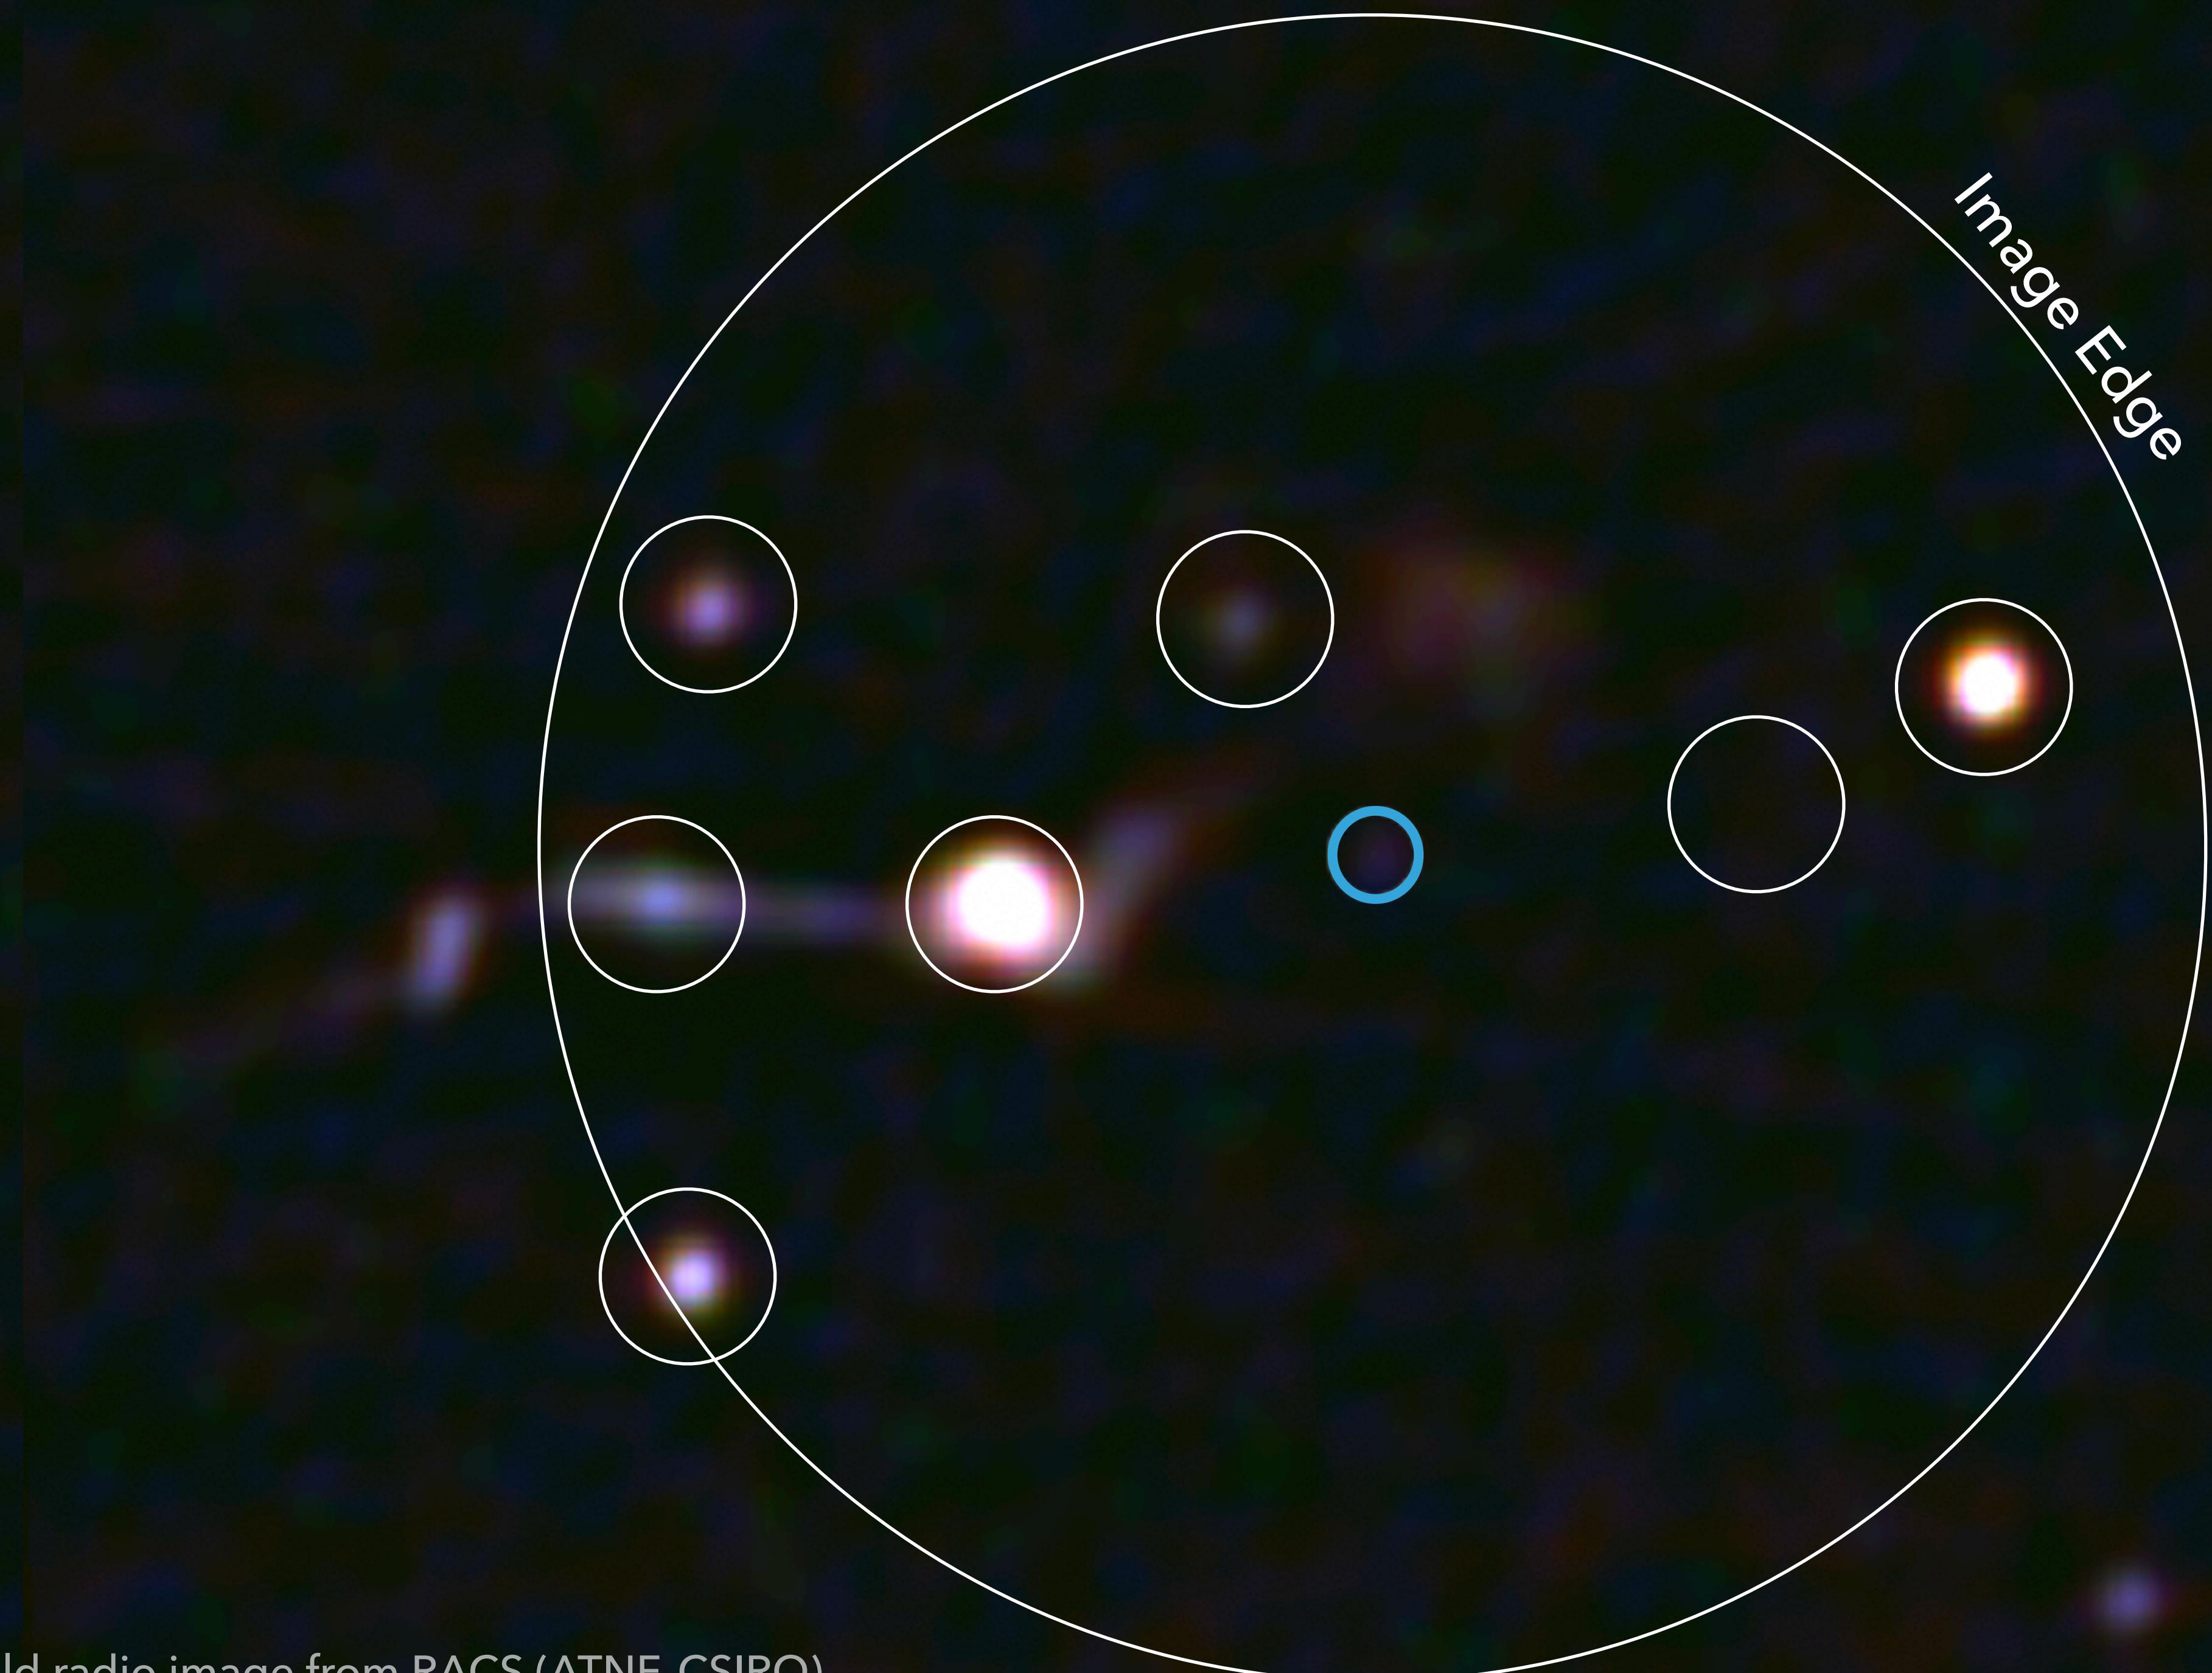

Optical survey image from SDSS9

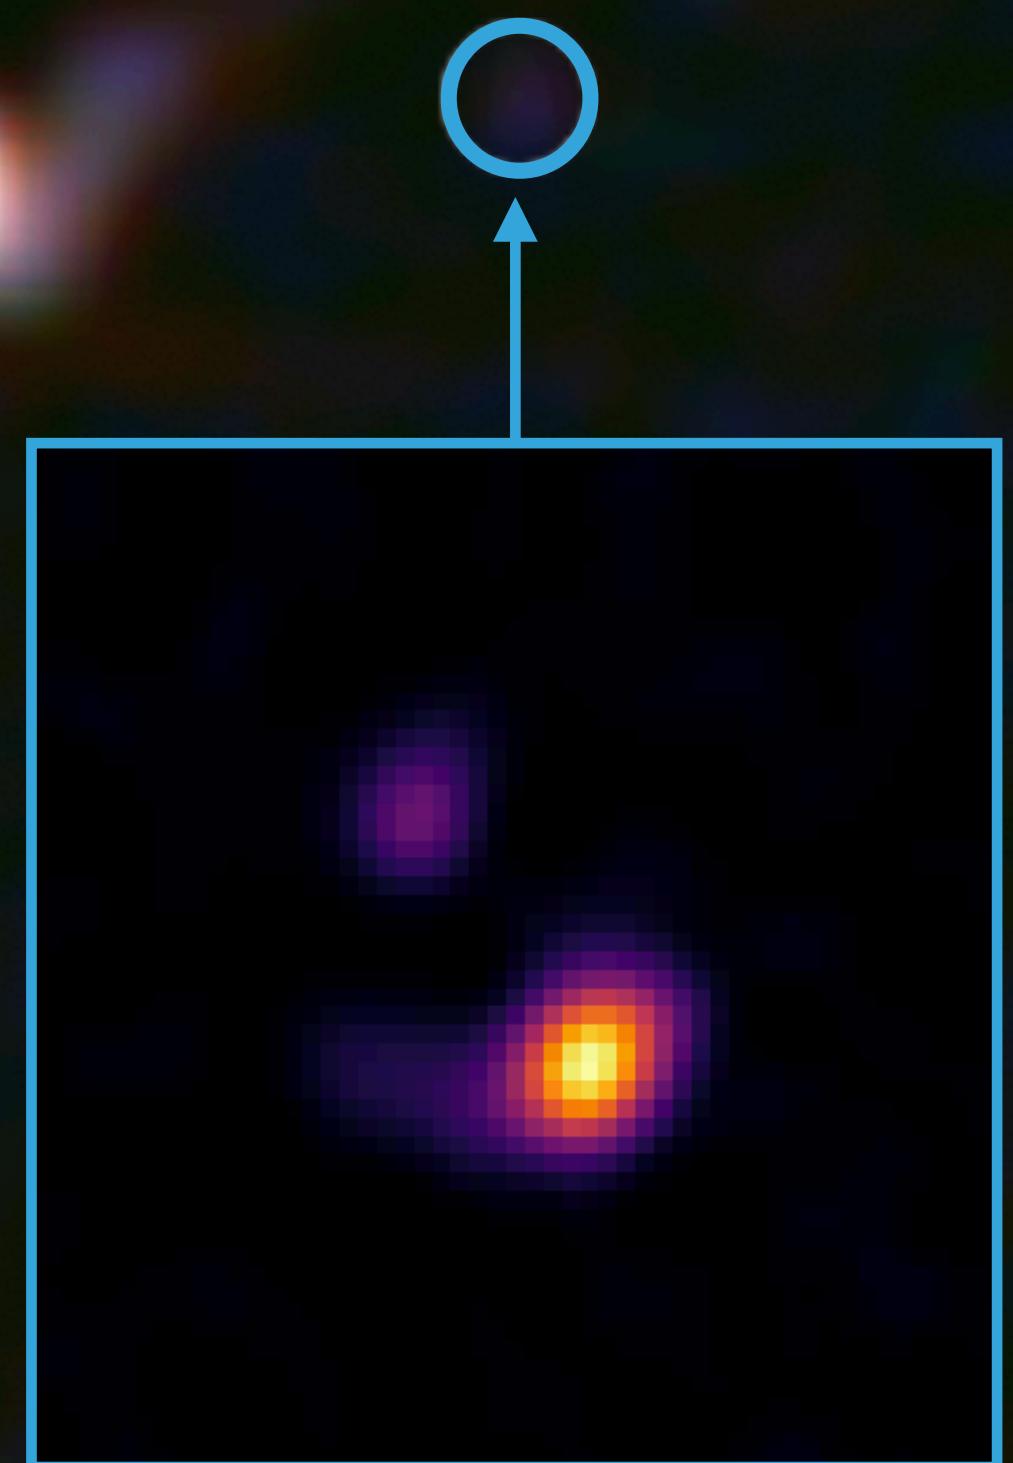

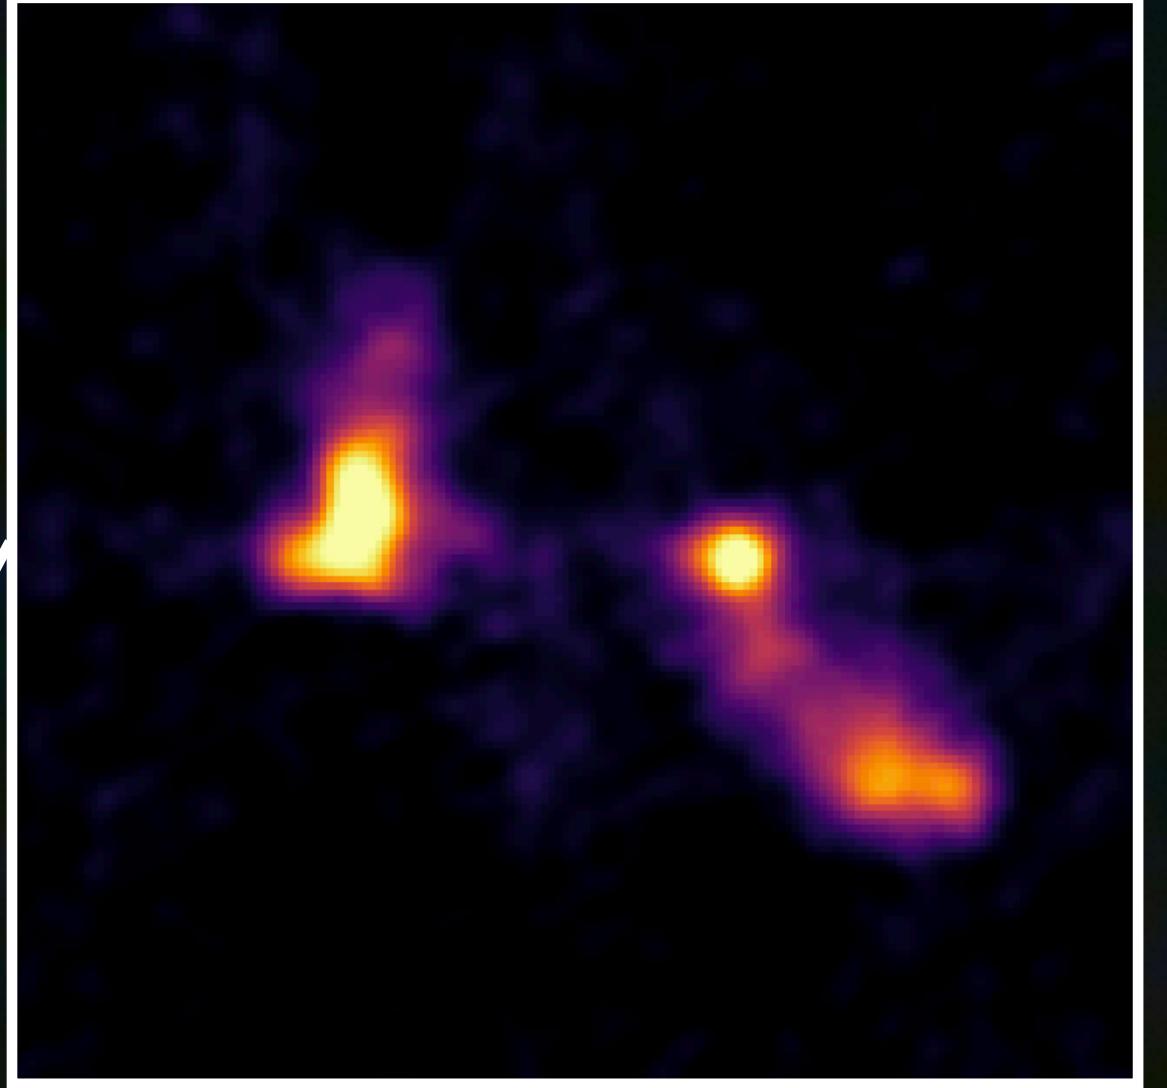

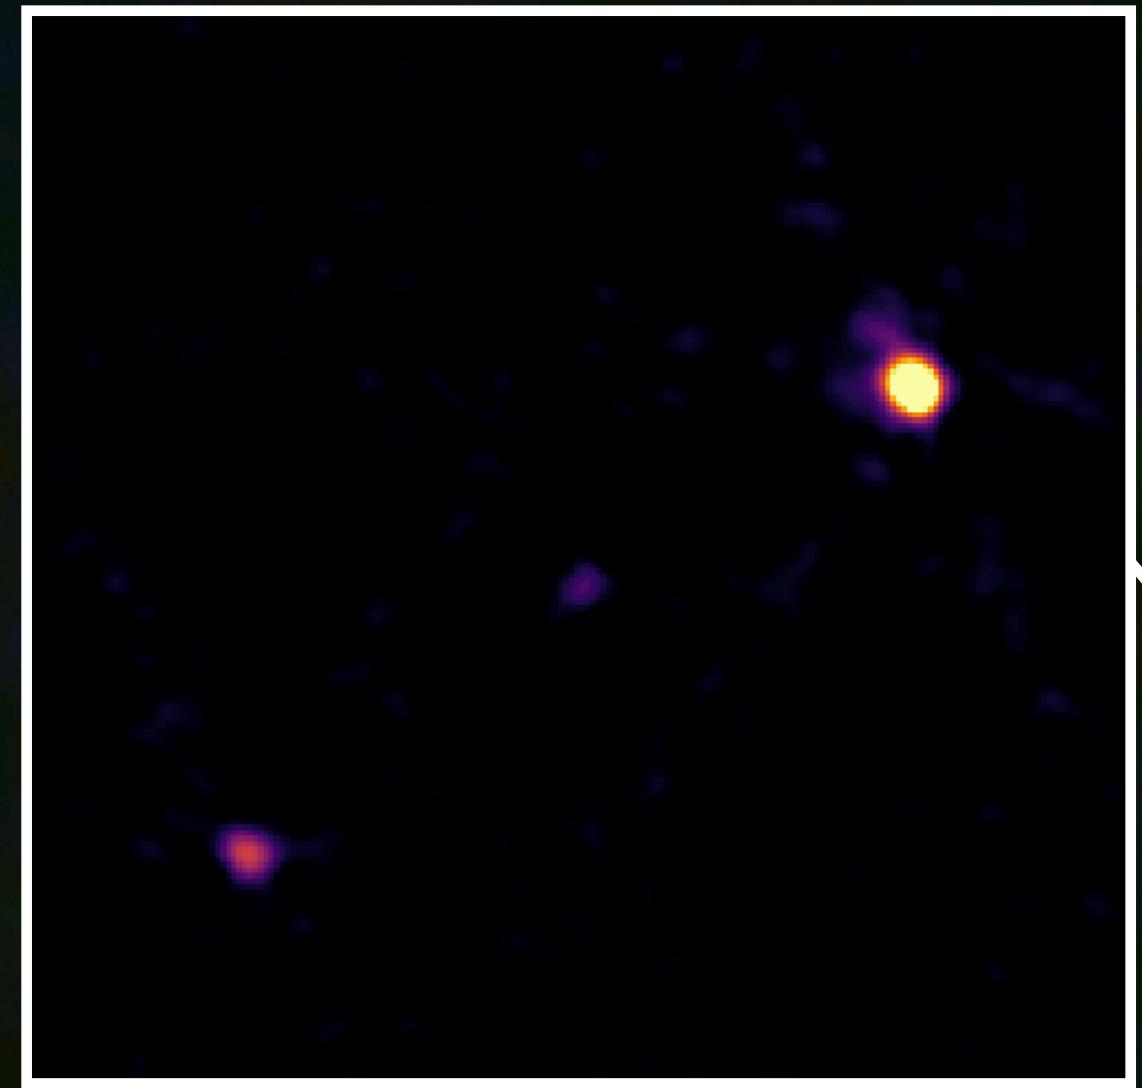

Optical survey image from SDSS9, close-up from DECaLS DR10

Optical survey image from SDSS9

Wide-field radio image from RACS (ATNF, CSIRO)

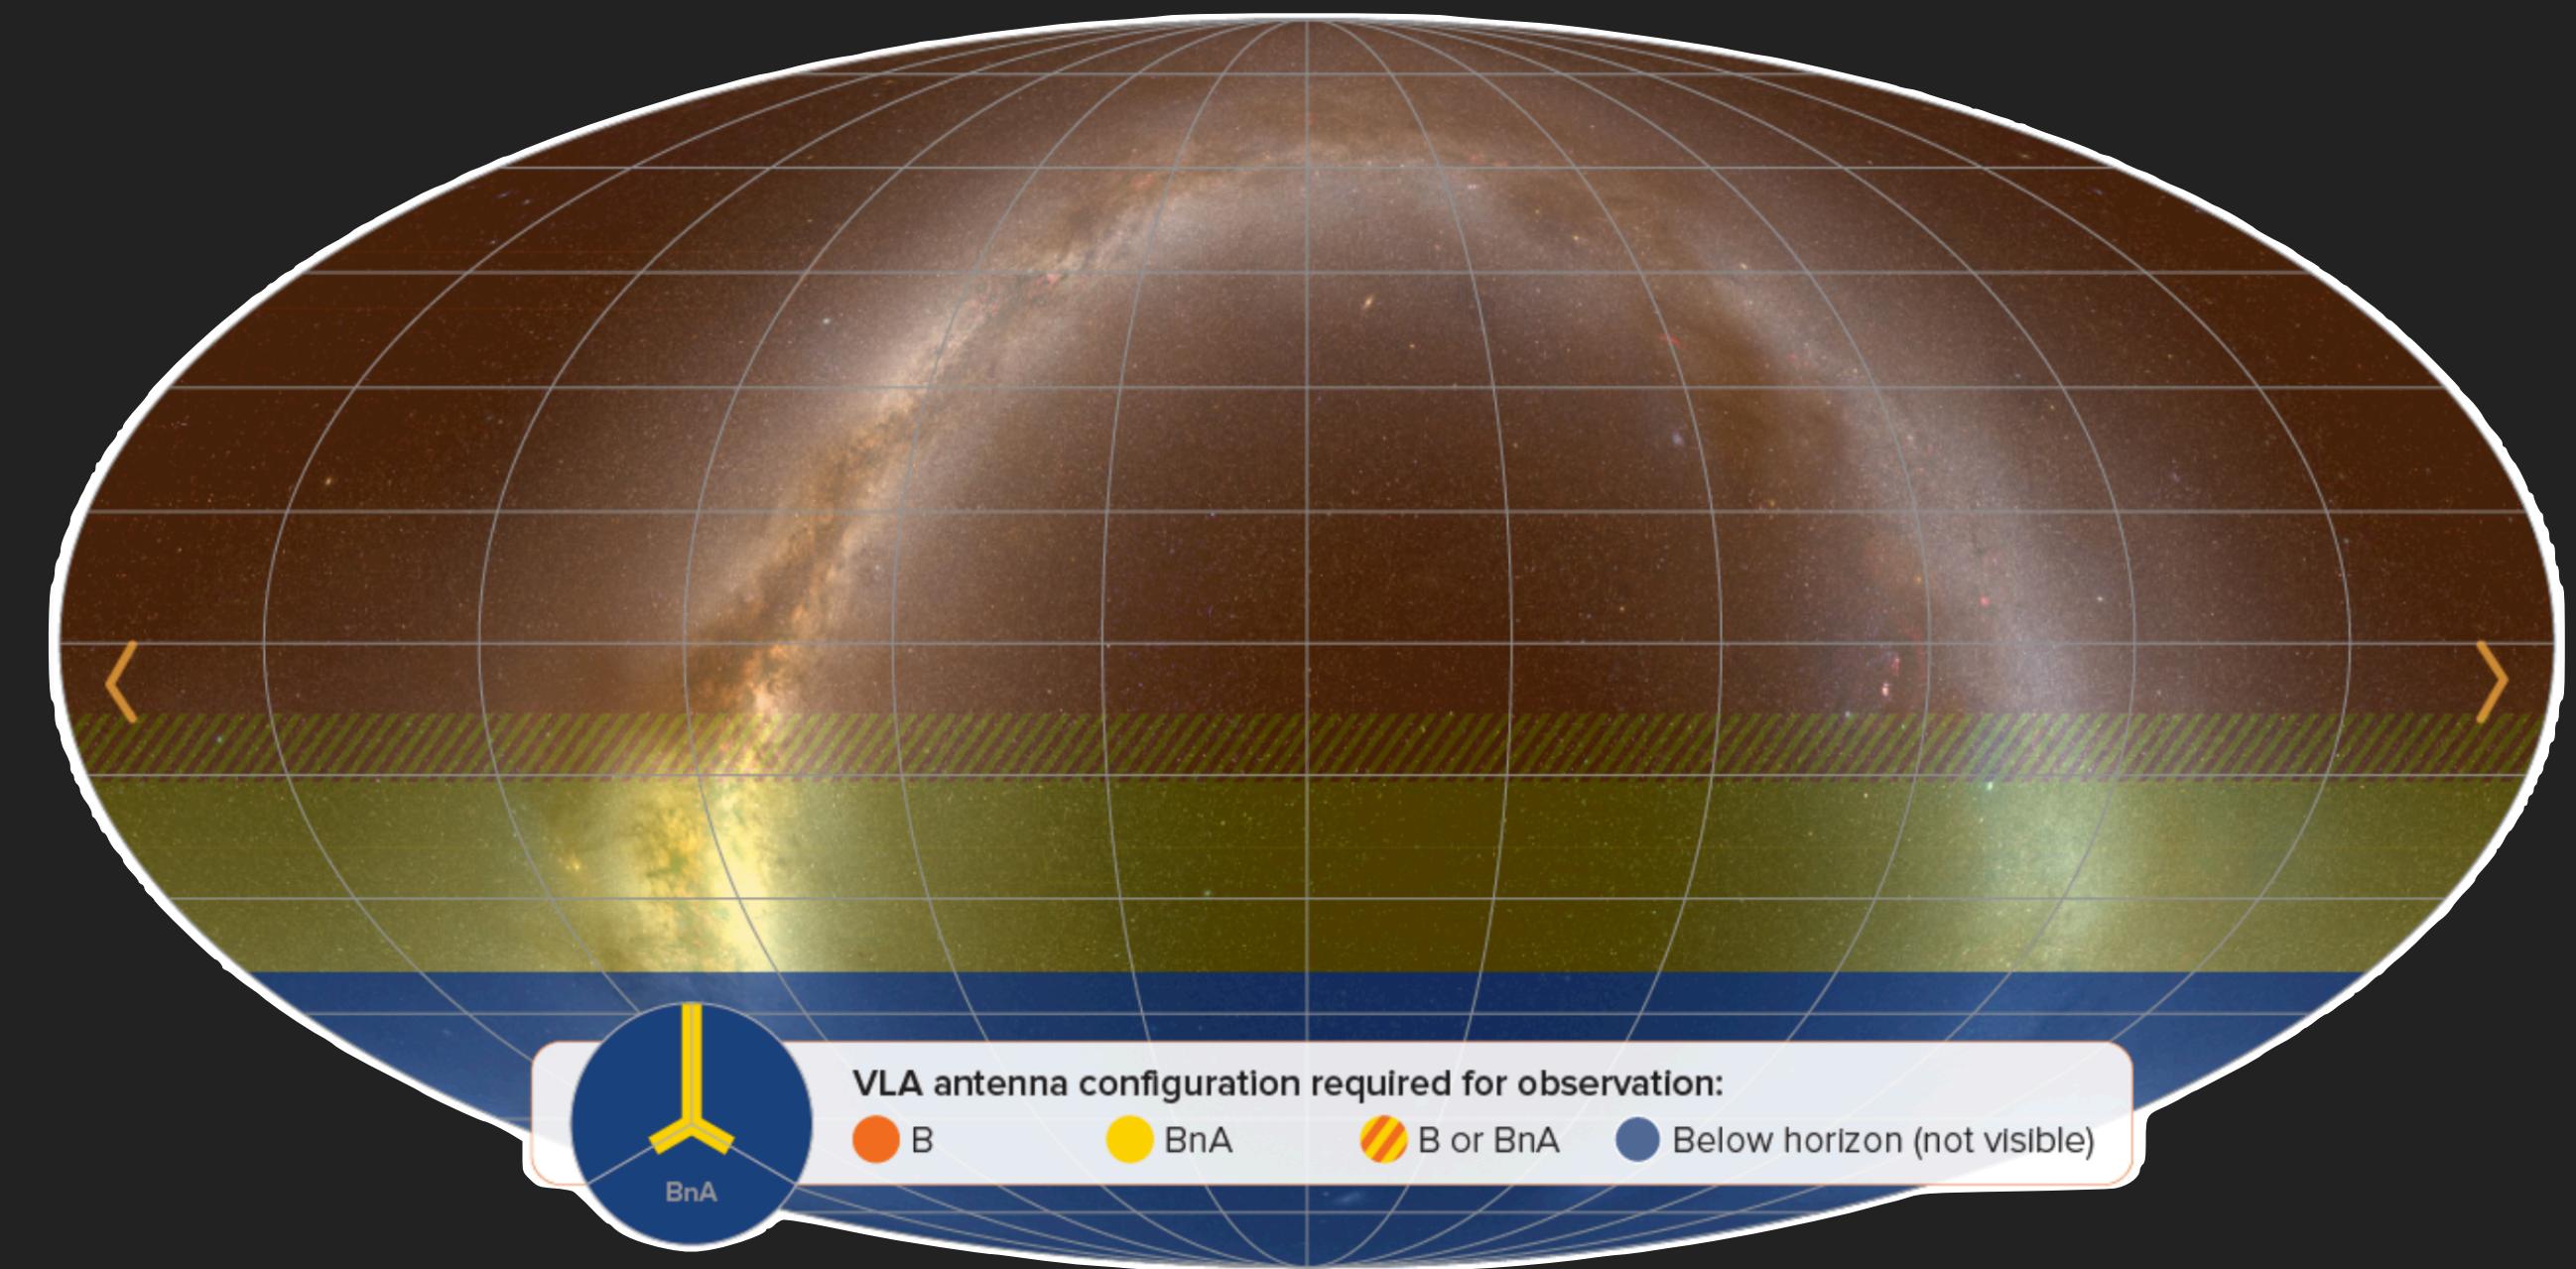

Wide-field radio image from RACS (ATNF, CSIRO)

# PROJECT 3: IMAGE STACKING

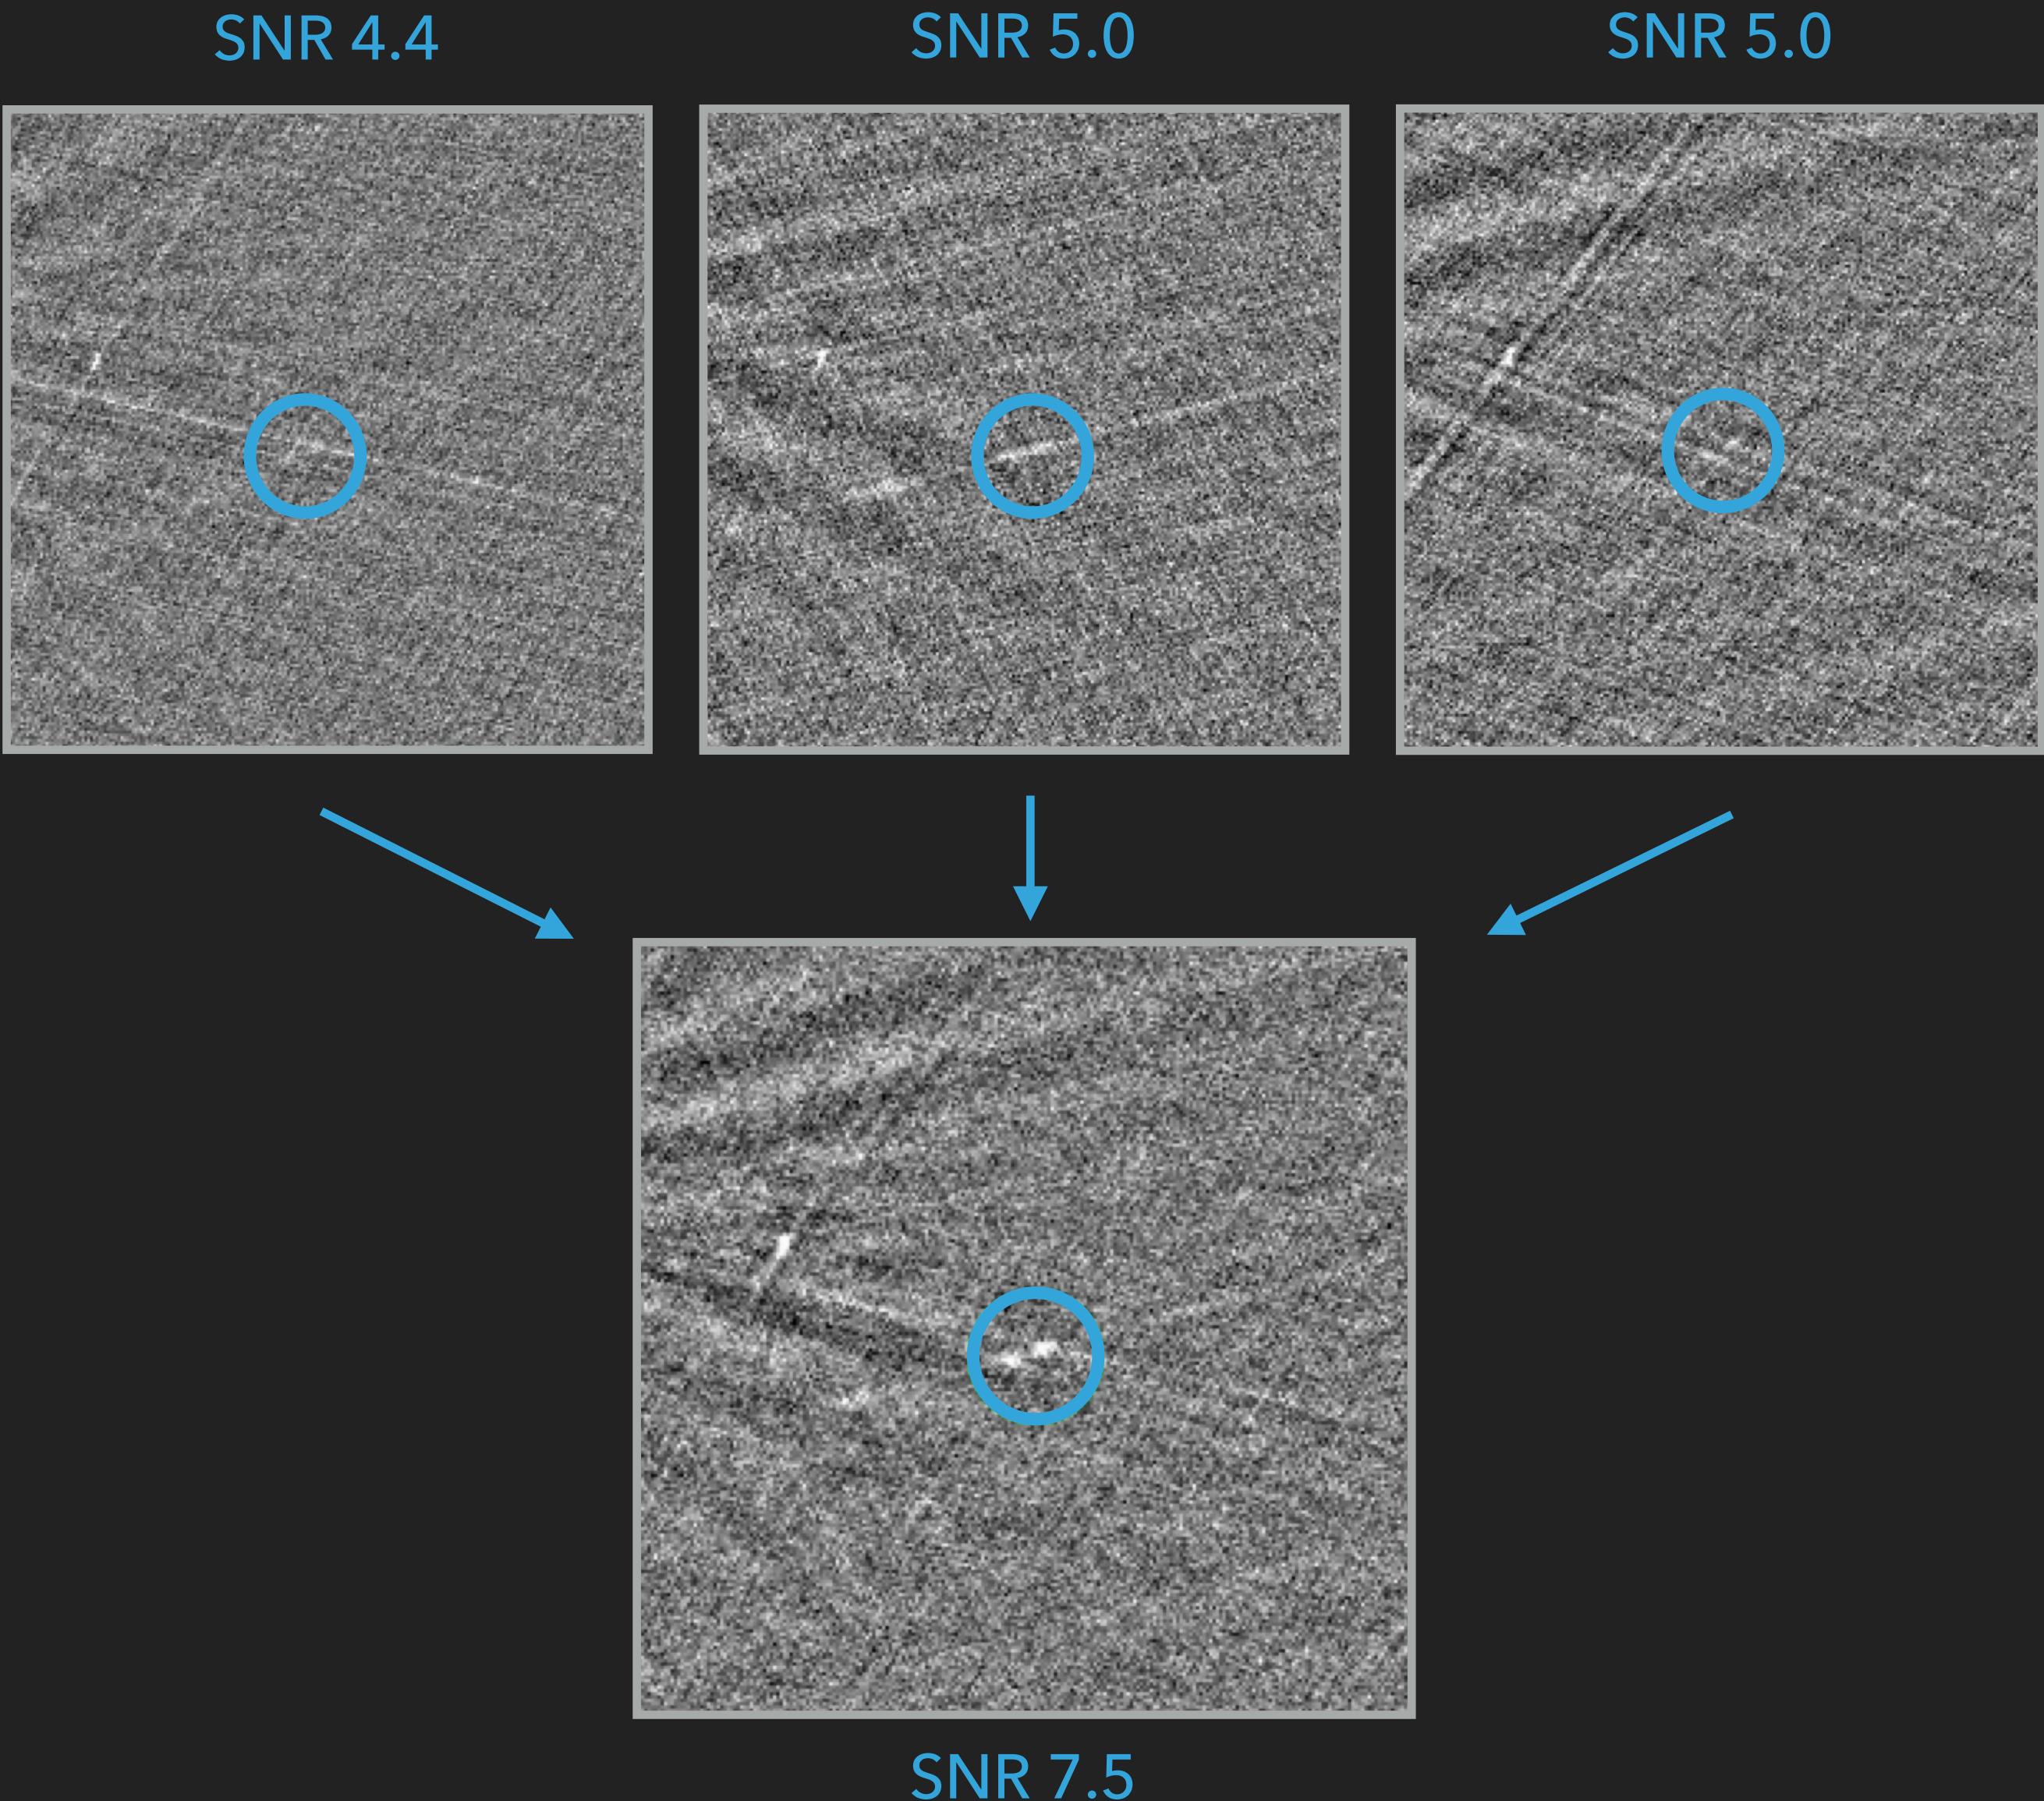

# THE VERY LARGE ARRAY SKY SURVEY

- ▶ Radio survey of 3/4ths of the sky
- ▶ Time variability survey: 3 epochs between 2017 and 2024
- ▶ Used to identify gravitational lens targets for high-resolution followup

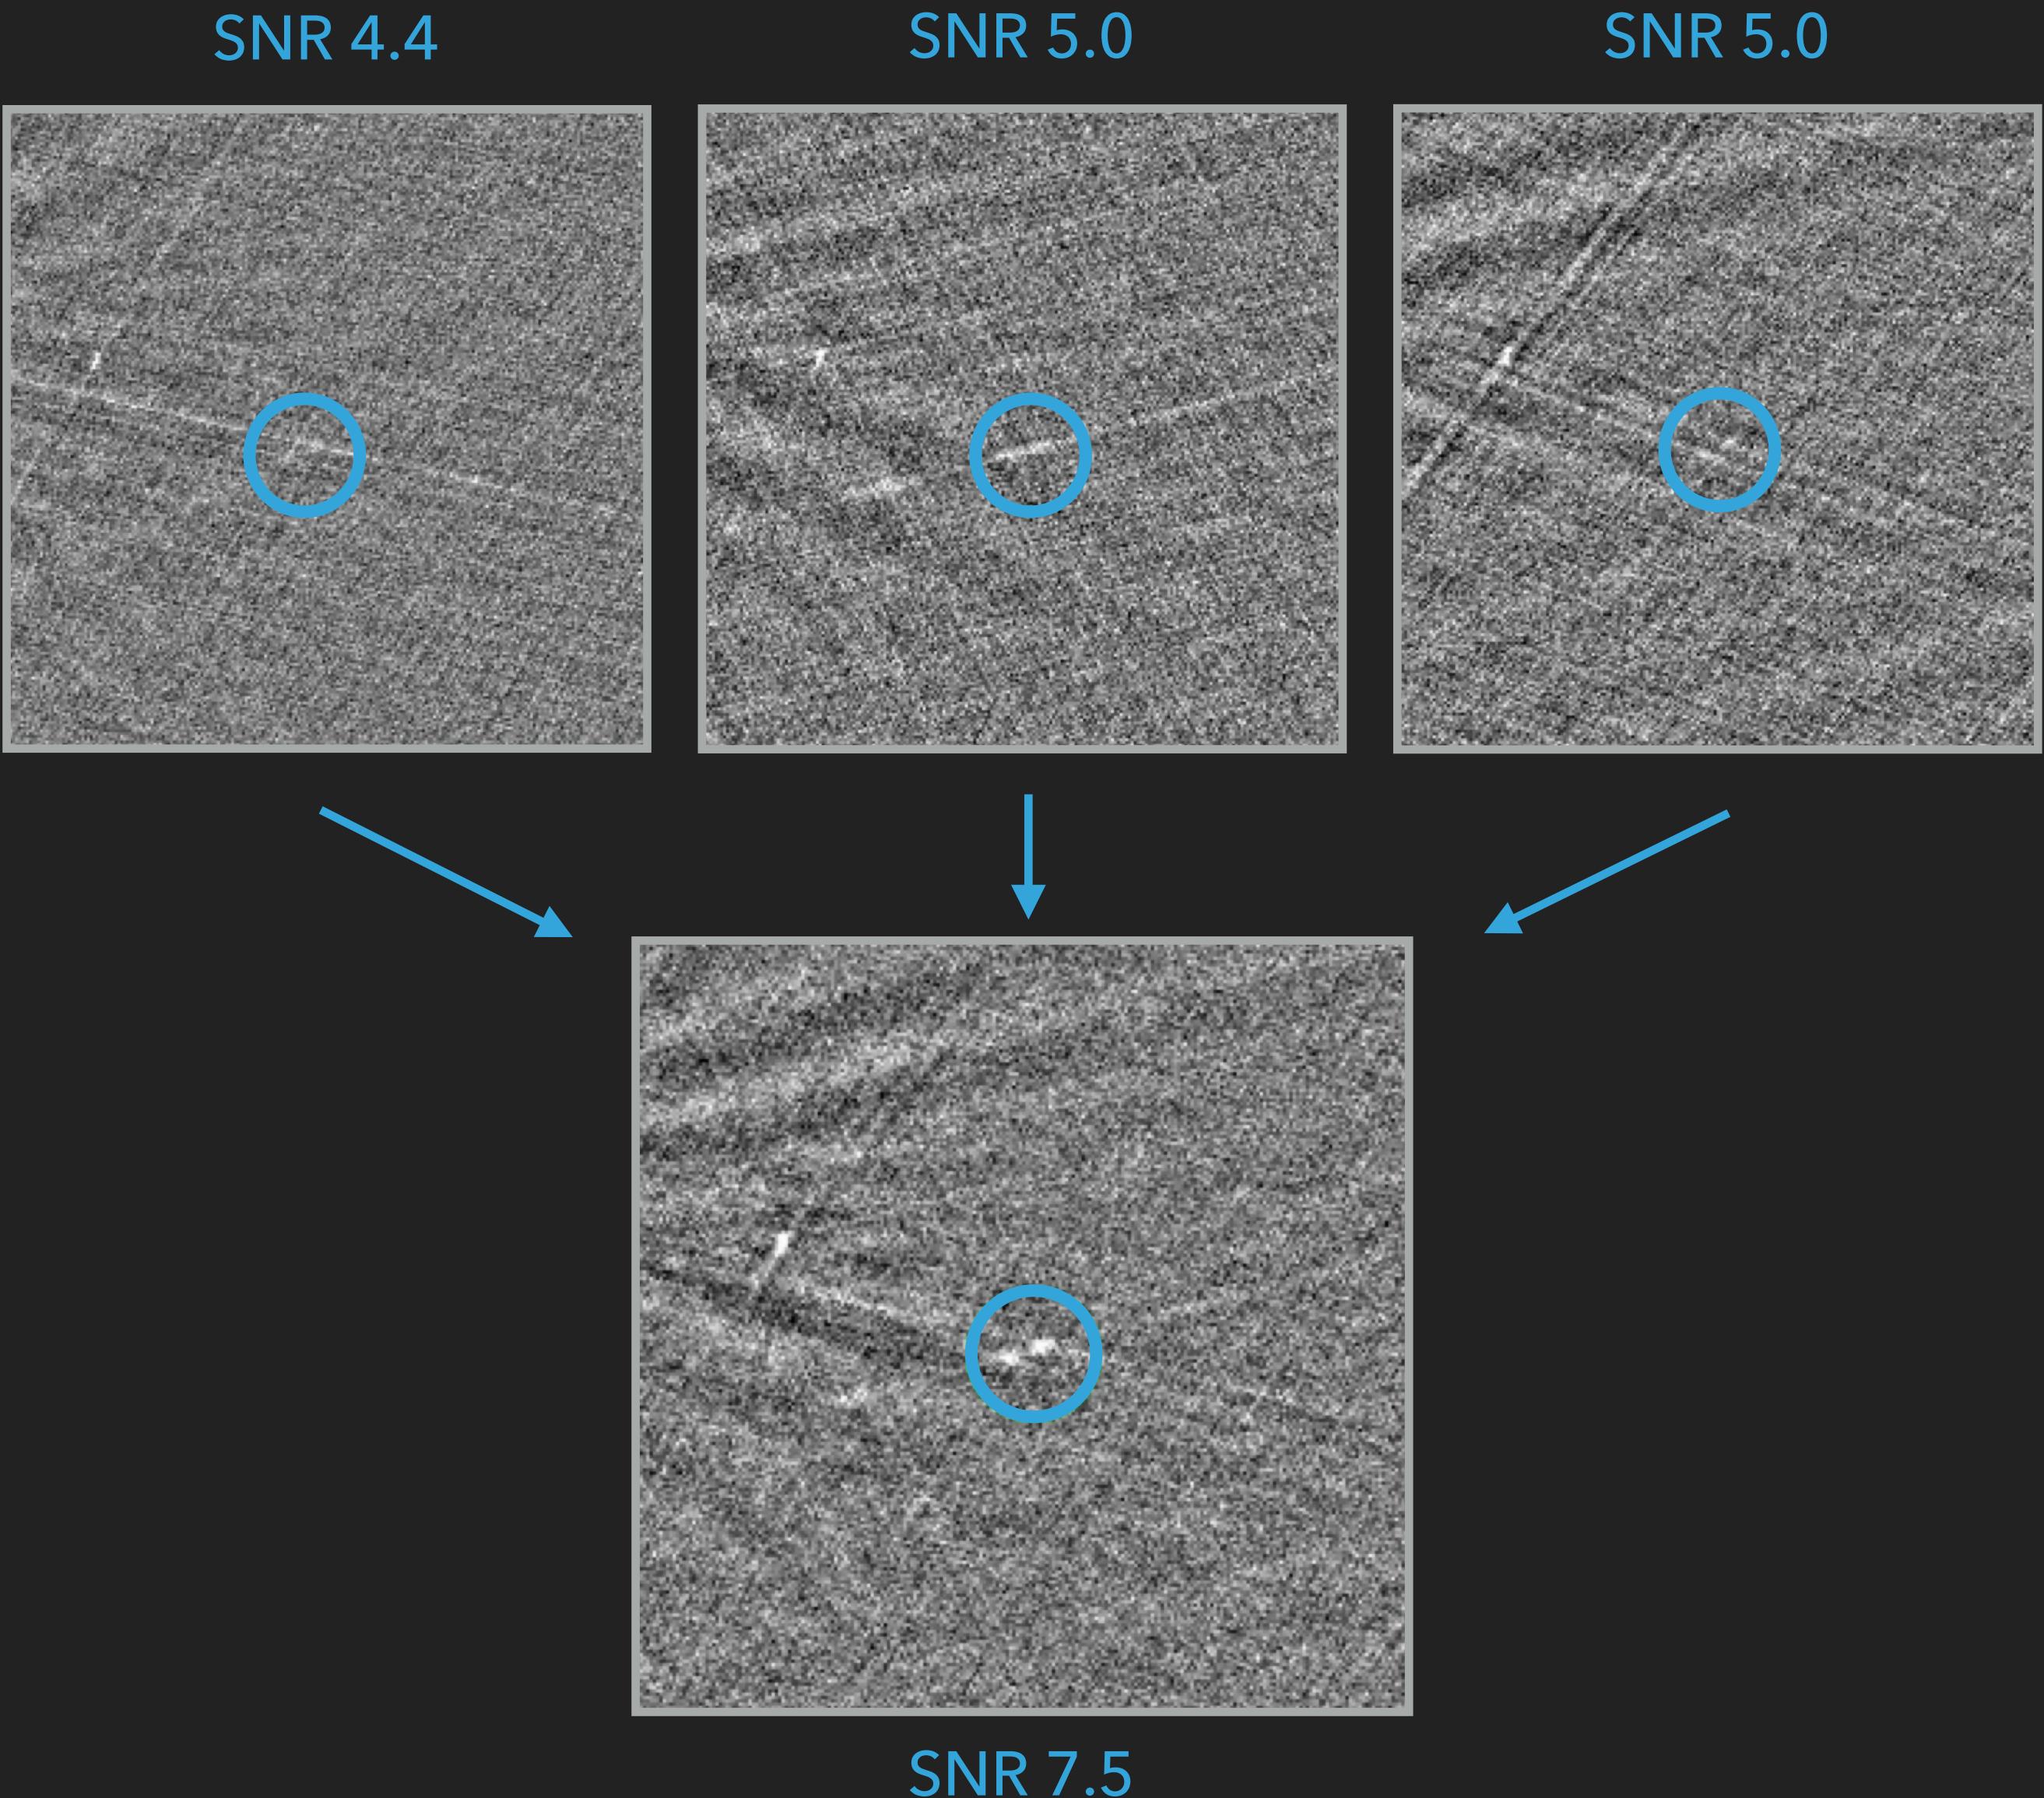

## IMAGE-PLANE VLASS STACKING

- ▶ Can achieve greater sensitivity by combining the three observational epochs
  - ▶ More lenses to observe
  - ▶ Laptop: about 5 minutes per square degree
  - ▶ Full survey is 30,000 square degrees
  - ▶ ~100 days on a laptop

## VLASS STACKING ON CHTC

- ▶ The perfect HTC use case?
- ▶ Each job runs one square degree
  - ▶ Stacks images, creates catalogs
- ▶ ~2 hours per job
- ▶ Entire survey theoretically stackable in 2 hours (given 30000 jobs)
- ▶ More realistically: 1 week?

## MOVING TO CHTC

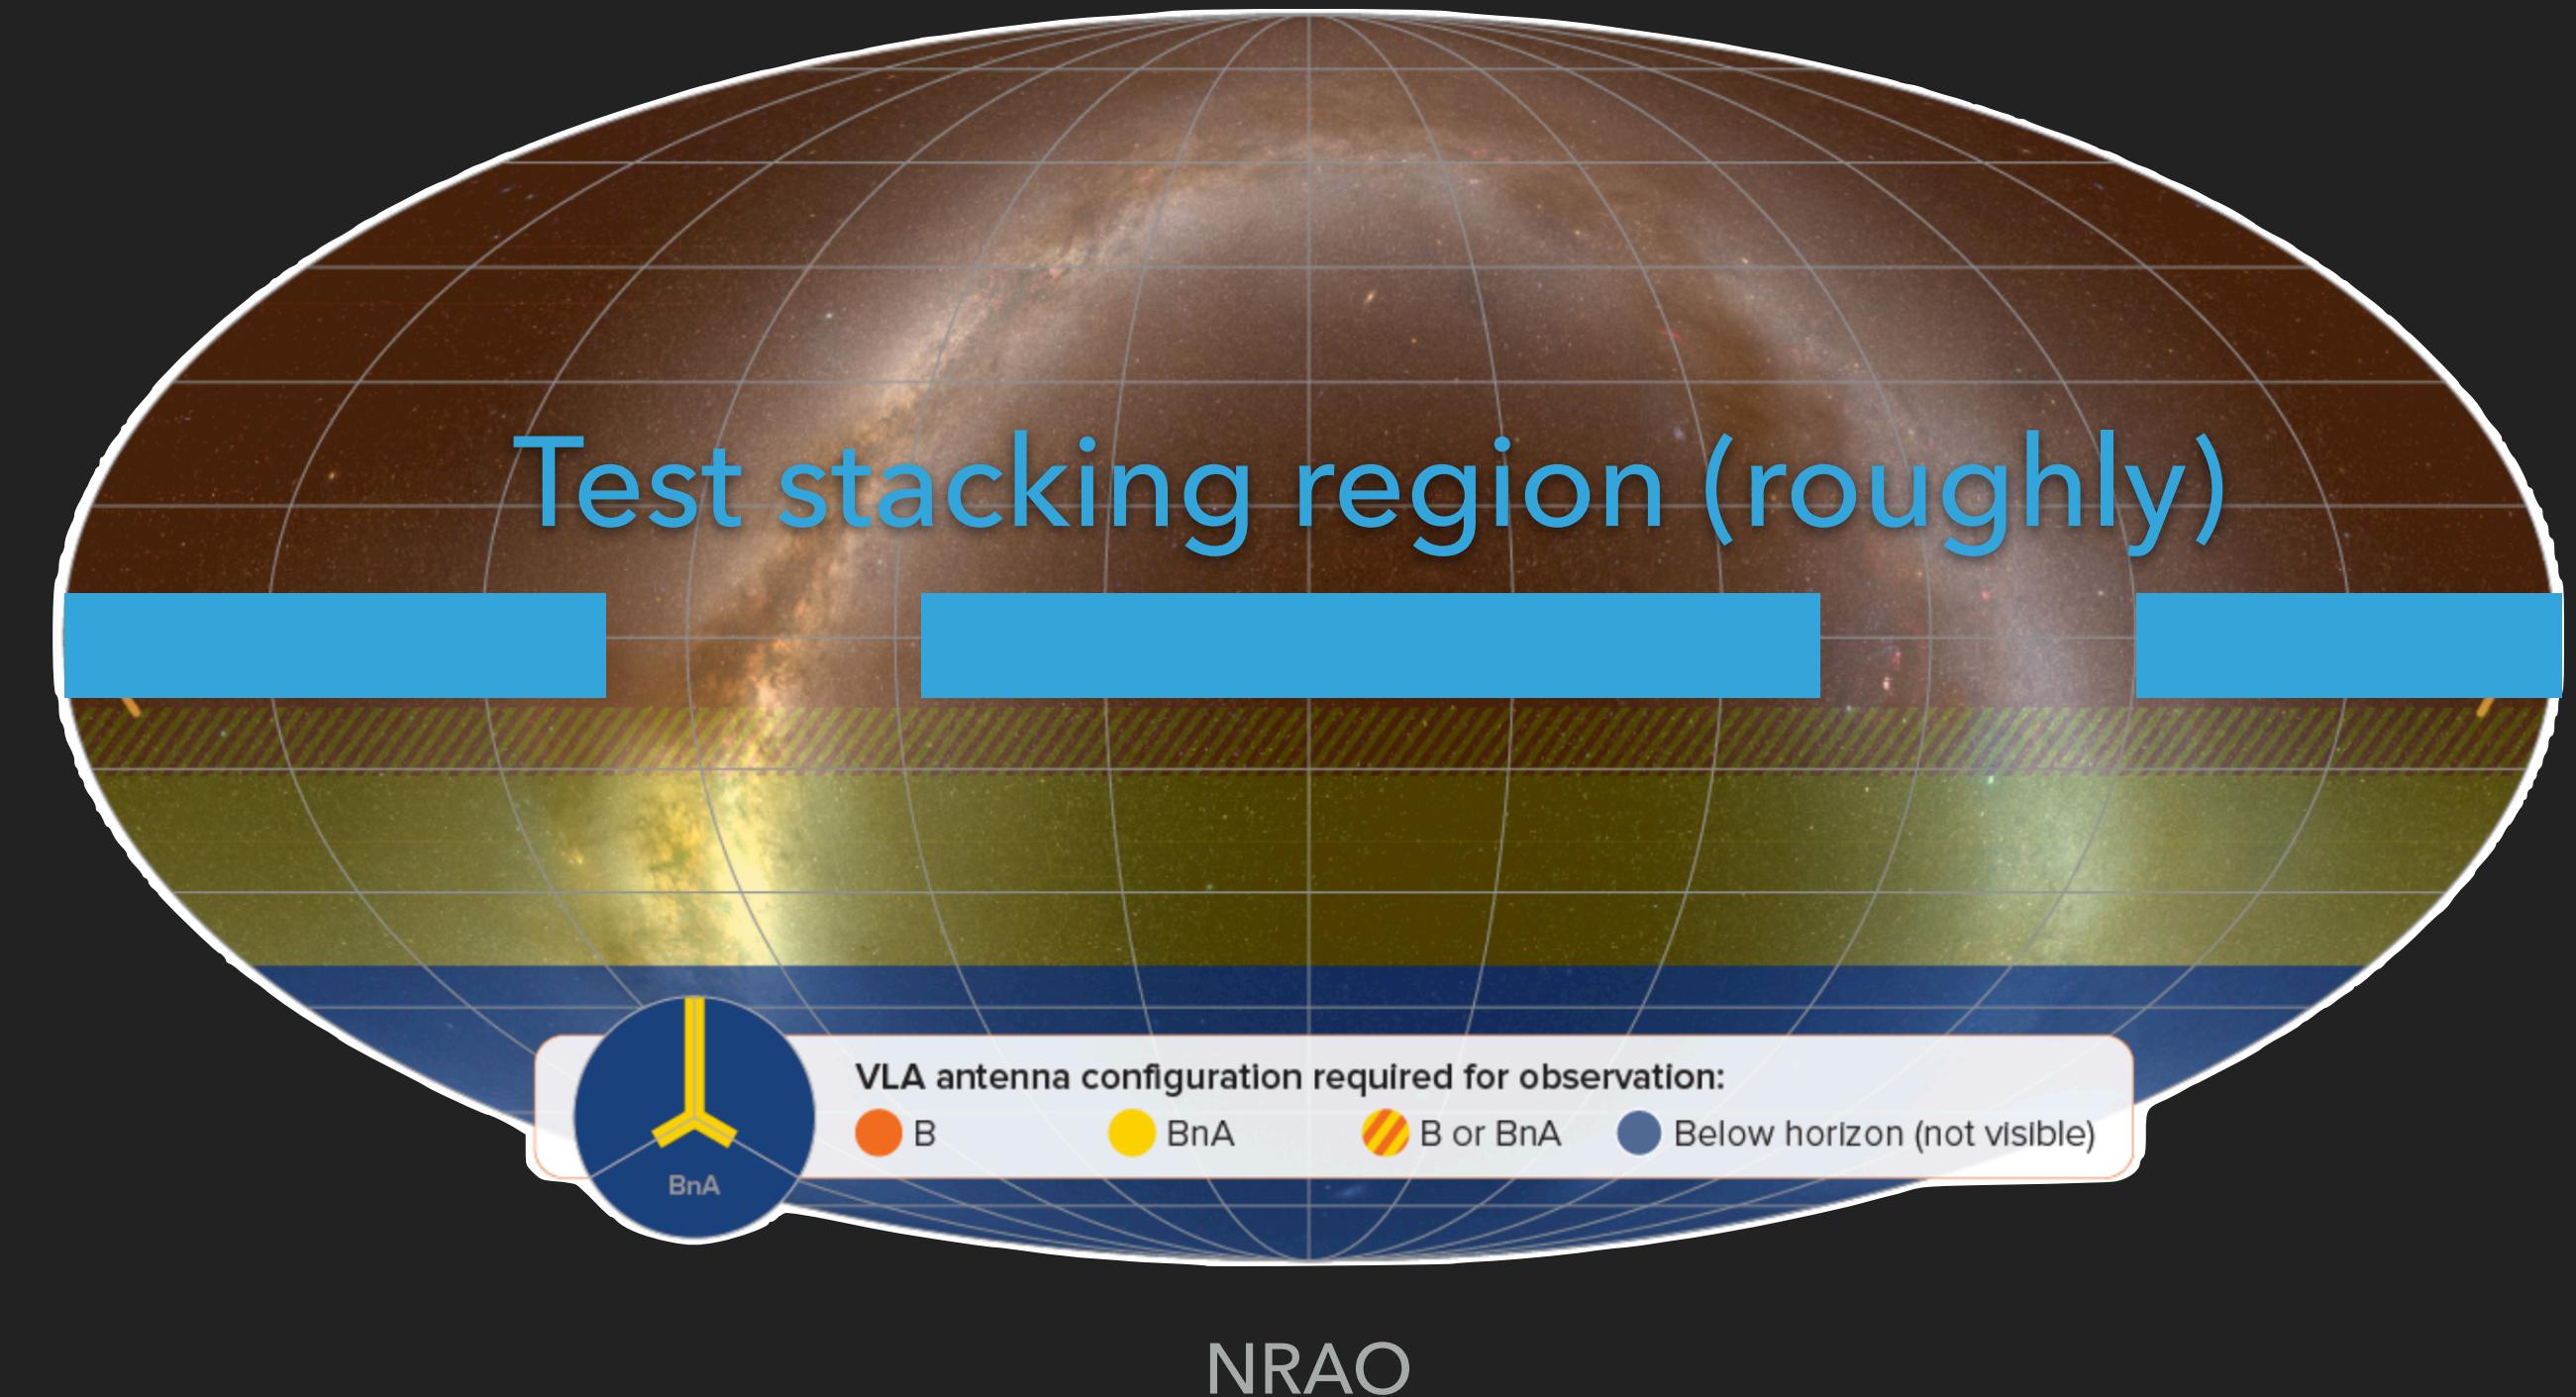

- ▶ Image transfer from a server rather than `/staging/`
- ▶ Each image needs different files
- ▶ Used a wrapper script to select a different line of a file per job, then run the stacking program
- ▶ Future challenge: getting image data off of CHTC for analysis

```
#!/bin/bash
#Wrapper script
head -n $1 tiles.txt | tail -n 1 > foo
sed 's/,/\n/g' foo > bar
wget -i bar
rm foo
rm bar
python3 stack_vlass.py
rm *.ql.*subim.fits
```

```
#Submission file
container_image = file:///staging/mnmartinez/stack.sif
plusone = $(Process) + 1
NewProcess = $INT(plusone,%d)
executable = stack_wrapper.sh
arguments = $(NewProcess)
should_transfer_files = YES
when_to_transfer_output = ON_EXIT_OR_EVICT
transfer_input_files = stack_vlass.py, tiles.txt
log = job_${Cluster}_${NewProcess}.log
error = job_${Cluster}_${NewProcess}.err
output = job_${Cluster}_${NewProcess}.out
requirements = (HasCHTCStaging == true)
request_cpus = 1
request_memory = 4GB
request_disk = 10GB
queue 40
```

## VLASS STACKING ON CHTC: CURRENT PROGRESS

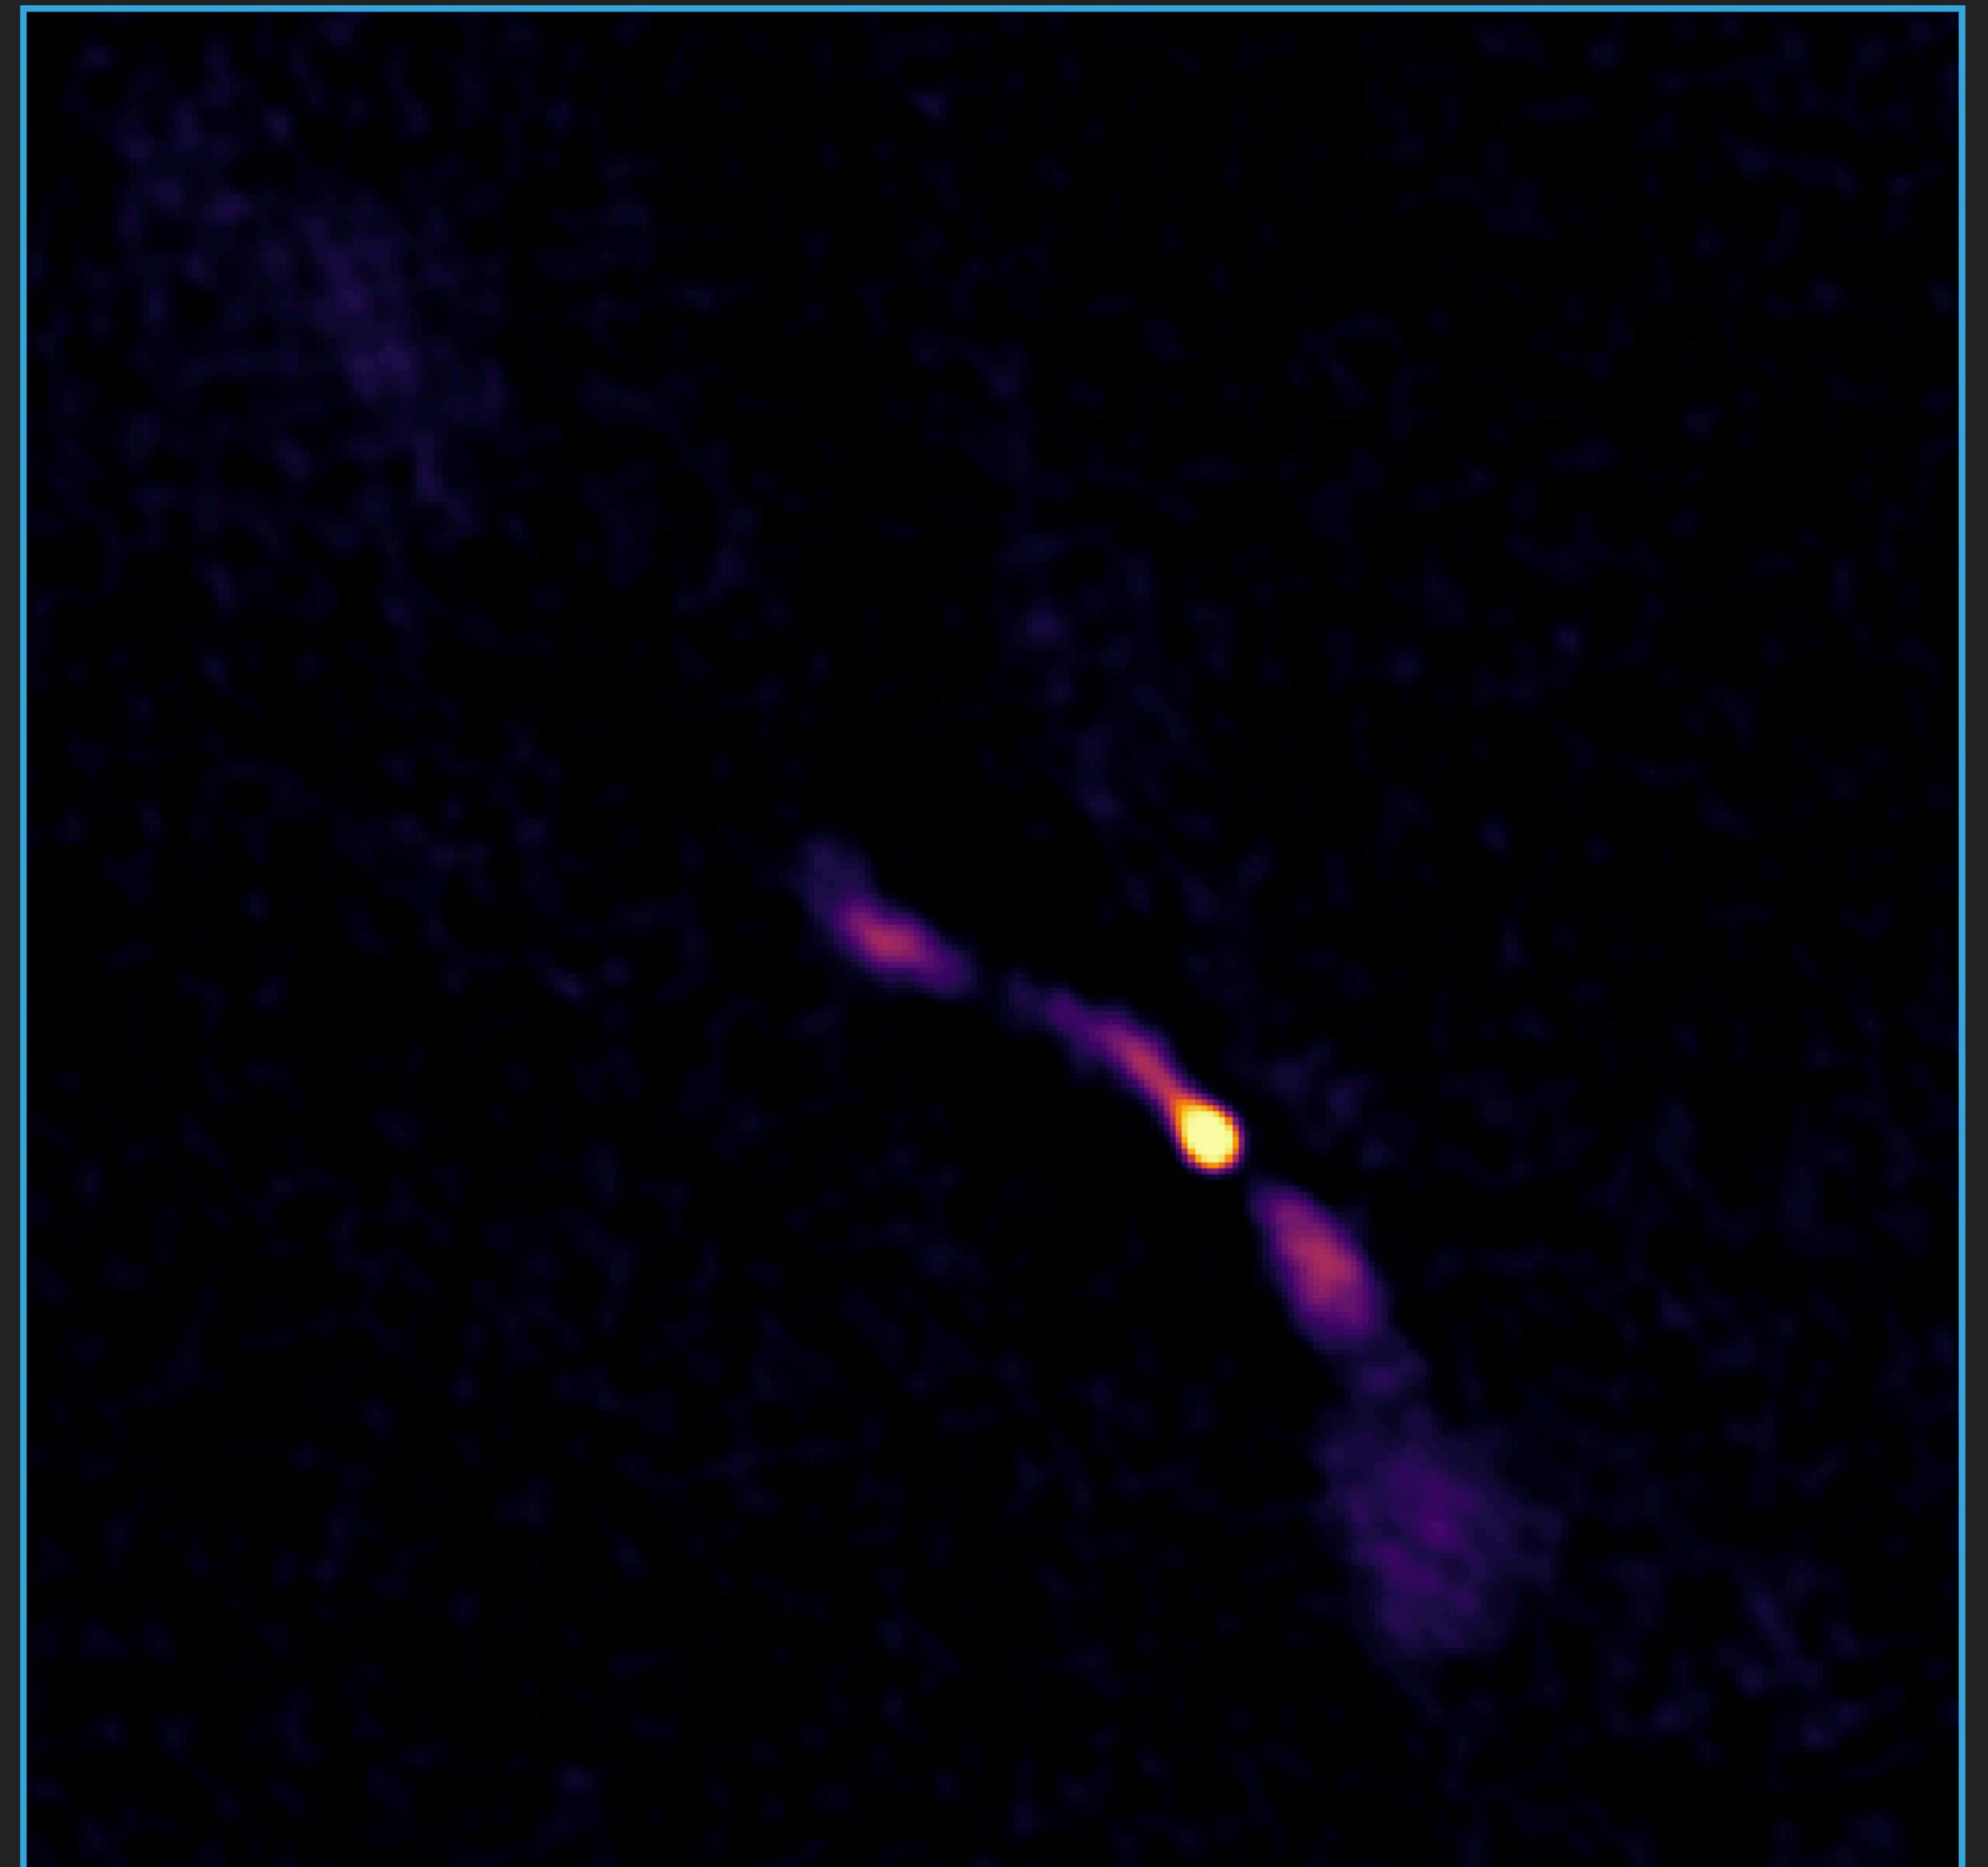

- ▶ Preliminary tests with ~40 square degrees have been promising
- ▶ Refine procedure/ensure image quality with smaller subset of sky (~1000 square degrees)
- ▶ Once details are ironed out, move to whole survey
- ▶ Undergraduate research at UW

NRAO

## CONCLUSION

- ▶ A research project has many different parts
  - ▶ Each part can have its own computing requirements
- ▶ Computing resources like CHTC or OSG can help with more than you might initially think!

# THE END

Questions welcome!
